Thus the true caufe of the origin of fountains remained undifcovered, till Dr Halley, in making his celeftial obfervations upon the tops of the mountains at St Helena, about 800 yards above the level of the fea, found, that the quantity of vapour which fell there (even when the fky was clear) was fo great, that it very much impeded his obfervations, by covering his glaffes with water every half quarter of an hour; and upon that he attempted to determine by experiment the quantity of vapour exhaled from the furface of the fea, as far as it rifes from heat, in order to try whether that might be a fufficient fupply for the water continually difcharged by fountains. The procefs of his experiment was as follows: He took a veffel of water falted to the fame degree with that of fea water, in which he placed a thermometer; and by means of a pan of coals brought the water to the fame degree of heat, which is obferved to be that of the air in our hotteft fummer; this done, he fixed the veffel of water with the thermometer in it to one end of a pair of fcales, and exactly counterpoifed it with weights on the other: then, at the end of two hours, he found, by the alteration made in the weight of the veffel, that about a fixtieth part of an inch of the depth of the water was gone off in vapour; and therefore, in twelve hours, one tenth of an inch would have gone off. Now this accurate obferver allows the Mediterranean fea to be forty degrees long; and four broad, (the broader parts compenfating for the narrower, fo that its whole furface is 160 fquare degrees); which, according to the experiment, muft yield at leaft 5,280,000,000 tons of water: In which account no regard is had to the wind and the agitation of the furface of the fea, both which undoubtedly promote the evaporation.

It remained now to compare this quantity of water with that which is daily conveyed into the fame fea by the rivers. The only way to do which was to compare them with fome known river; and accordingly he takes his computation from the river Thames; and, to avoid all objections, makes allowances, probably greater than what were abfolutely neceffary. Spring

The Mediterranean receives the following confiderable rivers, viz. the Iberus, the Rhone, the Tyber, the Po, the Danube, the Niefter, the Boryfthenes, the Tanais, and the Nile. Each of thefe he fuppofes to bring down ten times as much water as the Thames, whereby he allows for fmaller rivers which fall into the fame fea. The Thames, then, he finds by meafuration to difcharge about 20,300,000 tons of water a-day. If therefore the above-faid nine rivers yield ten times as much water as the Thames doth, it will follow, that all of them together yield but 1827 millions of tons in a day, which is but little more than one-third of what is proved to be raifed in vapour out of the Mediterranean in the fame time. We have therefore from hence a fource abundantly fufficient for the fupply of fountains.

Now having found that the vapour exhaled from the fea is a fufficient fupply for the fountains, he proceeds in the next place to confider the manner in which they are raifed; and how they are condenfed into water again, and conveyed to the fources of fprings.

In order to this he confiders, that if an atom of water was expanded into a fhell or bubble, fo as to be ten times as big in diameter as when it was water, that atom would become fpecifically lighter than air; and therefore would rife fo long as the warmth which firft feparated it from the furface of the water fhould continue to diftend it to the fame degree; and confequently, that vapours may be raifed from the furface of the fea in that manner, till they arrive at a certain height in the atmofphere, at which they find air of equal fpecific gravity with themfelves. Here they will float till, being condenfed by cold, they become fpecifically heavier than the air, and fall down in dew; or being driven by the winds againft the fides of mountains (many of which far furpafs the ufual height to which the vapours would of themfelves afcend), are compelled by the ftream of the air to mount up with it to the tops of them; where being condenfed into water, they prefently precipitate, and gleeting down by the crannies of the ftones, part of them enters into the caverns of the hills; which being once filled, all the overplus of water that comes thither runs over by the loweft place, and breaking out by the fides of the hills forms fingle fprings. Many of thefe running down by the valleys between the ridges of the hills, and coming to unite, form little rivulets or brooks: many of thefe again meeting in one common valley, and gaining the plain ground, being grown lefs rapid, become a river; and many of thefe being united in one common channel, make fuch ftreams as the Rhine and the Danube; which latter, he obferves, one would hardly think to be a collection of water condenfed out of vapour, unlefs we confider how vaft a tract of ground that river drains, and that it is the fum of all thofe fprings which break out on the fouth fide of the Carpathian mountains, and on the north fide of the immenfe ridge of the Alps, which is one continued chain of mountains from Switzerland to the Black fea.

Thus one part of the vapours which are blown on the land is returned by the rivers into the fea from whence it came. Another part falls into the fea before it reaches the land; and this is the reafon why the rivers do not return fo much water into the Mediterra-

Spring. nean as is raifed in vapour. A third part falls on the low lands, where it affords nourifhment to plants; yet it does not reft there, but is again exhaled in vapour by the action of the fun, and is either carried by the winds to the fea to fall in rain or dew there, or elfe to the mountains to become the fources of fprings.

However, it is not to be fuppofed that all fountains are owing to one and the fame caufe; but that fome proceed from rain and melted fnow, which, fubfiding through the furface of the earth, makes its way into certain cavities, and thence iffues out in the form of fprings; becaufe the waters of feveral are found to increafe and diminifh in proportion to the rain which falls: that others again, efpecially fuch as are falt, and fpring near the fea-fhore, owe their origin to fea-water percolated through the earth; and fome to both thefe caufes: though without doubt moft of them, and efpecially fuch as fpring near the tops of high mountains, receive their waters from vapours, as before explained.

This reafoning of Dr Halley's is confirmed by more recent obfervations and difcoveries. It is now found, that though water is a tolerable conductor of the electric fluid, dry earth is an electric *per fe*, confequently the dry land muft always be in an electrified ftate compared with the ocean, unlefs in fuch particular cafes as are mentioned under the article EARTHQUAKE, N° 82. It is alfo well known, that fuch bodies as are in an electrified ftate, whether *plus* or *minus*, will attract vapour, or other light fubftances that come near them. Hence the vapours that are raifed from the ocean muft neceffarily have a tendency to approach the land in great quantity, even without the affiftance of the wind, though this laft muft undoubtedly contribute greatly towards the fame purpofe, as Dr Halley juftly obferves. In like manner, the higher grounds are always in a more electrified ftate than the lower ones: and hence the vapours having once left the ocean and approached the fhore, are attracted by the high mountains; of which Mr Pennant gives an inftance in Snowdon. Hence we may fee the reafon why fprings are fo common in the neighbourhood of mountains, they being fo advantageoufly formed in every refpect for collecting and condenfing the vapours into water.

The heat of fprings is generally the fame with the mean temperature of the atmofphere. The mean temperature of the fouth of England is 48°; in Scotland, near Edinburgh, it is 45°; in the north of Ireland it is 48°, and on the fouth coaft about 51°. At Upfal, in Sweden, it is 43°, and in Paris 53°. According to accurate experiments made by eminent philofophers, the heat of the fprings in thefe different countries correfponds with the medium temperature. We have not heard that fimilar experiments have been made in other countries, or we fhould have been careful to collect them. We do not, however, doubt but they have been made in moft countries of Europe; yet we fufpect little attention has been paid to this fubject within the tropical regions.

Though this coincidence of the heat of fprings with the mean temperature of the climate where they flow, feems to be a general fact, yet it admits of many exceptions. In many parts of the world there are fprings which not only exceed the mean temperature, but even the ftrongeft meridian heat ever known in the torrid regions. The following table will give a diftinct notion of the degrees of heat which different fprings have been found to poffefs, according to the experiments of philofophers. It is neceffary to remark, that experiments made upon the fame fprings, made by different perfons, vary a little from one another, which may be owing to many accidents eafily accounted for. Where this is the cafe, we fhall mention both the loweft and higheft degree of heat which has been afcribed to the fame fpring, according to Fahrenheit's thermometer.

In cold countries, where congelation takes place, the heat of the earth is confiderably above the freezing point, and continues fo through the whole year. From experiments that have been made in mines and deep pits, it appears that this heat is uniform and ftationary at a certain depth. But as the heat of thefe fprings far exceeds the common heat of the internal parts of the earth, it muft be occafioned by caufes peculiar to certain places; but what thefe caufes are it is no eafy matter to determine. We are certain, indeed, that hot fprings receive their heat from fome fubterranean caufe; but it is a matter of difficulty to inveftigate how this heat is produced and preferved. Theories, however, have been formed on this fubject. The fubterranean heat has been afcribed to the electrical fluid, and to a great body of fire in the centre of the earth: But we fufpect that the nature of the electrical fluid and its effects are not fufficiently underftood. As to the fuppofition that the heat of fprings is owing to a central fire, it is too hypothetical to require any refutation. From what then does this heat originate, and whence is the fuel which has produced it for fo many ages? To enable us to anfwer thefe queftions with precifion, more information is neceffary than we have hitherto obtained refpecting the ftructure of the internal parts of the earth. It is peculiarly requifite that we fhould be made acquainted with the foffils which are moft common in thofe places where hot fprings abound. We fhould then perhaps difcover that hot fprings always pafs through bodies of a combuftible nature. It is well known to chemifts, that when water is mixed with the vitriolic acid, a degree of heat is produced fuperior to that of boiling water. It is alfo an eftablifhed fact, that when water meets with pyrites, that is, a mixture of fulphur and iron, a violent inflammation takes place. If, therefore, we could prove that thefe materials exift in the ftrata from which hot fprings are derived, we fhould be enabled to give a fatisfactory account of this curious phenomenon. As fome apology for this fuppofition, we may add, that moft of the hot fprings mentioned above have been found by analyfis to be impregnated with fulphur, and fome of them with iron.

Spring ‖ Spruce-Beer.

iron. It muſt, however, be acknowledged, that the hot ſprings of Iceland, which are 212°, the heat of boiling water, according to an accurate analyſis of their contents by the ingenious Dr Black, were neither found to contain iron nor ſulphur. It will therefore, perhaps, be neceſſary that we ſhould wait with patience, and continue to collect facts, till the ſciences of chemiſtry and mineralogy ſhall be ſo far advanced as to enable us to form a permanent theory on this ſubject.

Gray's Letters from Germany and Switzerland.

Springs are of different kinds. Some are perennial, or continue to flow during the whole year; others flow only during the rainy ſeaſon; ſome ebb and flow. At Torbay there is one of this kind, which ebbs and flows five or ſix inches every hour. There is another near Coriſo in Italy, which ebbed and flowed three times a-day in the time of Pliny, and continues to do ſo ſtill. A ſpring near Henly ſometimes flows for two years together, and then dries up for an equal period. For the ingredients found in ſprings, ſee *MINERAL-Waters*.

SPRING, in *Mechanics*, denotes a thin piece of tempered ſteel, or other elaſtic ſubſtance, which being wound up ſerves to put machines in motion by its elaſticity, or endeavours to unbend itſelf; ſuch is the ſpring of a watch, clock, or the like.

SPRING, *Ver*, in coſmography, denotes one of the ſeaſons of the year; commencing, in the northern parts of the world, on the day the ſun enters the firſt degree of Aries, which is about the 10th day of March, and ending when the ſun leaves Gemini; or, more ſtrictly and generally, the ſpring begins on the day when the diſtance of the ſun's meridian altitude from the zenith, being on the increaſe, is at a medium between the greateſt and leaſt. The end of the ſpring coincides with the beginning of ſummer. See SUMMER.

Elater SPRING, in *Phyſics*, denotes a natural faculty or endeavour of certain bodies, to return to their firſt ſtate, after having been violently put out of it by compreſſing, or bending them. This faculty is, by philoſophers, uſually denominated *elaſtic force*, or *elaſticity*.

SPRING-Tide. See ASTRONOMY *Index*, and TIDE.

Burning SPRINGS. See *BURNING-Springs*.

SPRINGER, or *SPRING-Bok*. See CAPRA, MAMMALIA *Index*.

SPRIT, a ſmall boom or pole which croſſes the ſail of a boat diagonally, from the maſt to the upper hindmoſt corner of the ſail, which it is uſed to extend and elevate; the lower end of the ſprit reſts in a ſort of wreath or collar called the *ſnotter*, which encircles the maſt in that place.

SPRITSAIL. See SAIL and SHIP.

SPRITSAIL-Topſail. See SAIL and SHIP.

SPRUCE-TREE. See PINUS, BOTANY *Index*.

SPRUCE-Beer, a cheap and wholeſome liquor, which is thus made: Take of water 16 gallons, and boil the half of it. Put the water thus boiled, while in full heat, to the reſerved cold part, which ſhould be previouſly put into a barrel or other veſſel; then add 16 pounds of treacle or molaſſes, with a few table ſpoonfuls of the eſſence of ſpruce, ſtirring the whole well together; add half a pint of yeaſt, and keep it in a temperate ſituation, with the bung hole open, for two days, till the fermentation be abated. Then cloſe it up or bottle it off, and it will be fit for being drunk in a few days afterwards. In North America, and perhaps in other countries, where the black and white ſpruce-firs abound, inſtead of adding the *eſſence* of the ſpruce at the ſame time with the molaſſes, they make a decoction of the leaves and ſmall branches of theſe trees, and find the liquor equally good. It is a powerful antiſcorbutic, and may prove very uſeful in long ſea voyages.

Spruce-Beer ‖ Square.

SPUNGE, or SPONGE. See SPONGIA.

SPUNGING, in *Gunnery*, the cleaning of the inſide of a gun with a ſponge, in order to prevent any ſparks of fire from remaining in it, which would endanger the life of him that ſhould load it again.

SPUN-YARN, among ſailors, is a kind of line made from rope yarn, and uſed for ſeizing or faſtening things together.

SPUNK. See BOLETUS, BOTANY *Index*.

SPUR, a piece of metal conſiſting of two branches encompaſſing a horſeman's heel, and a rowel in form of a ſtar, advancing out behind to prick the horſe.

SPUR-Winged Water-Hen. See PARRA, ORNITHOLOGY *Index*.

SPURGE. See EUPHORBIA, } BOTANY *Index*.
SPURGE-Laurel. See DAPHNE, }
SPURREY. See SPERGULA, }

SPY, a perſon hired to watch the actions, motions, &c. of another; particularly what paſſes in a camp. When a ſpy is diſcovered, he is hanged immediately.

SQUADRON, in military affairs, denotes a body of horſe whoſe number of men is not fixed; but is uſually from 100 to 200.

SQUADRON of Ships, either implies a detachment of ſhips employed on any particular expedition, or the third part of a naval armament.

SQUADS, in a military ſenſe, are certain diviſions of a company into ſo many ſquads, generally into three or four. The uſe of forming companies into as many ſquads of inſpection as it has ſerjeants and corporals, is proved by thoſe regiments who have practiſed that method; as by it the irregularity of the ſoldiers is conſiderably reſtrained, their dreſs improved, and the diſcipline of the regiment in general moſt remarkably forwarded. Every officer ſhould have a roll of his company by ſquads.

SQUALL, a ſudden and violent blaſt of wind, uſually occaſioned by the interruption and reverberation of the wind from high mountains. Theſe are very frequent in the Mediterranean, particularly that part of it which is known by the name of the *Levant*, as produced by the repulſion and new direction which the wind meets with in its paſſage between the various iſlands of the Archipelago.

SQUALUS, the SHARK; a genus of fiſhes arranged by Linnæus under the claſs of amphibia, and the order of nantes, but by Gmelin referred to the claſs of fiſhes, and order of chondropteryii. See ICHTHYOLOGY *Index*.

SQUAMARIA. See LATHRÆA, BOTANY *Index*.

SQUAMOUS, in *Anatomy*, a name given to the ſpurious or falſe ſutures of the ſkull, becauſe compoſed of ſquamæ or ſcales like thoſe of fiſhes.

SQUARE, in *Geometry*, a quadrilateral figure both equilateral and equiangular. See GEOMETRY.

SQUARE-Root. See ALGEBRA and ARITHMETIC, N° 32. and 34.

Hollow SQUARE, in the military art, a body of foot drawn

Square, Squaring.

drawn up with an empty ſpace in the middle, for the colours, drums, and baggage, faced and covered by the pikes every way to keep off the horſe.

SQUARE, among *Mechanics*, an inſtrument conſiſting of two rules or branches, faſtened perpendicularly at one end of their extremities, ſo as to form a right angle. It is of great uſe in the deſcription and menſuration of right angles, and laying down perpendiculars.

T SQUARE, or *Tee Square*, an inſtrument uſed in drawing, ſo called from its reſemblance to the capital letter T.

SQUARE-Rigged, an epithet applied to a ſhip whoſe yards are very long. It is alſo uſed in contradiſtinction to all veſſels whoſe ſails are extended by ſtays or lateen-yards, or by booms and gaffs; the uſual ſituation of which is nearly in the plane of the keel; and hence,

SQUARE-Sail, is a ſail extended to a yard which hangs parallel to the horizon, as diſtinguiſhed from the other ſails which are extended by booms and ſtays placed obliquely. This ſail is only uſed in fair winds, or to ſcud under in a tempeſt. In the former caſe, it is furniſhed with a large additional part called the *bonnet*, which is then attached to its bottom, and removed when it is neceſſary to SCUD. See SCUDDING.

SQUARING, or *QUADRATURE of the Circle*, ſignifies the finding a ſquare exactly equal to the area of a given circle. This problem however has not been, and probably cannot be, ſtrictly reſolved by the commonly admitted principles of geometry; mathematicians having hitherto been unable to do more than to find a ſquare that ſhall differ from the area of any propoſed circle by as ſmall a quantity as they pleaſe. The quadrature of the circle is a problem of the ſame degree of difficulty, and indeed may be regarded as identical with another geometrical problem, namely, the *Rectification of the circle*, or the finding a ſtraight line equal to its circumference; for the area of a circle is equal to that of a rectangle contained by the radius and a ſtraight line equal to half the circumference (GEOMETRY, Sect. VI. Prop. 3.): therefore, if a ſtraight line exactly equal to the circumference could be found, a rectilineal ſpace preciſely equal to the area might alſo be found, and the contrary. But although no perfectly accurate reſolution of the problem has been obtained under either form, we can always find approximate values of the area and circumference; and therefore it is now cuſtomary to apply the terms *quadrature* and *rectification* of the circle alſo to theſe.

The problem of the quadrature of the circle appears to have engaged the attention of geometers at a very early period; for we are told that Anaxagoras, who lived about 500 years before Chriſt, attempted its ſolution while confined in priſon on account of his philoſophical opinions. We are ignorant of the reſult of his reſearches; but although we cannot ſuppoſe they were attended with any ſucceſs, we may reaſonably conclude that we are indebted to them for the diſcovery of ſome of the properties of the figure, which are now known as elementary propoſitions in geometry.

Hippocrates of Chios was likewiſe engaged in trying to reſolve the ſame problem, and it was no doubt in the courſe of his inquiries into this ſubject that he diſcovered the quadrature of the curvilineal ſpace, which is now known by the name of the *Lune* of Hippocrates. The nature of this diſcovery may be briefly explained as follows. Let ABCD be a circle (Plate D. fig. 1.), H its centre, AC its diameter, ADC a triangle inſcribed in the ſemicircle, having its ſides AD, DC equal to one another. On D as a centre, with DA or DC as a radius, let the quadrantal arch AEC be deſcribed, then ſhall the curvilineal ſpace bounded by the ſemicircle ABC and the quadrantal arch AEC (which is the *Lune* of Hippocrates) be equal to the rectilineal triangle ADC. For becauſe circles are to one another as the ſquares of the radii (GEOMETRY, Sect. VI. Prop. 4.); the circle having DA for its radius will be to the circle having HA for its radius as the ſquare of DA to the ſquare of HA, that is, as 2 to 1; hence the former of theſe circles will be double the latter, and conſequently one fourth of the former will be equal to one half of the latter; that is, the quadrant AECD will be equal to the ſemicircle ABC; from theſe equals take away the common ſpace bounded by the diameter AC and the arch AEC, and there will remain the triangle ADC equal to the lunular ſpace AECBA.

Squaring. Plate D. Fig. 1.

Although Hippocrates's diſcovery has led to no important concluſion either relating to the quadrature of the circle or that of any other curve, yet at the time it was made it might be regarded as of ſome conſequence, chiefly becauſe it ſhewed the poſſibility of exhibiting a rectilineal figure equal to a ſpace bounded by curve lines, a thing which we have reaſon to ſuppoſe was then done for the firſt time, and might have been fairly doubted, conſidering the inſuperable difficulty that was found to attend the quadrature of the circle or its rectification.

Ariſtotle ſpeaks of two perſons, viz. Bryſon and Antiphon, who about his time, or a little earlier, were occupied with the quadrature of the circle. The former appears, according to the teſtimony of Alexander Aprodiſeus, to have erred moſt egregiouſly; he having concluded that the circumference was exactly $3\frac{1}{4}$ times the diameter. And the latter ſeems to have proceeded pretty much in the ſame manner as Archimedes afterwards did in ſquaring the parabola, that is, by firſt inſcribing a ſquare in the circle, then an iſoſceles triangle in each of the ſegments of the curve, having for its baſe a ſide of the ſquare; and next again a ſeries of triangles in the ſegments, having for their baſes the ſides of the former ſeries, and ſo on: this mode of procedure however, could not be attended with any ſucceſs, as it is well known that the ſpaces thus formed do not, as in the caſe of the parabola, admit of being abſolutely ſummed.

It may naturally be ſuppoſed that Archimedes exerted his utmoſt efforts to reſolve this problem; and probably it was only after long meditation on the ſubject that he loſt all hopes of ſucceſs, and contented himſelf with that approximation to the ratio of the diameter to the circumference which is contained in his treatiſe *De Circuli Dimenſione*, which has been preſerved from the period in which he wrote, about 250 years before Chriſt, to the preſent times. He found his approximation to the ratio, by ſuppoſing a regular polygon of 96 ſides to be deſcribed about the circle, and another of the ſame number of ſides to be inſcribed in it, and by ſhewing that the perimeter of the circumſcribing polygon was leſs than $3\frac{10}{70}$, or $3\frac{1}{7}$ times the diameter, but that the perimeter of the inſcribed figure was greater than $3\frac{10}{71}$ times the

SQUARING or Quadrature of the Circle. Plate II.

Squaring.

the diameter; now the circumference of the circle being lefs than the perimeter of the one polygon but greater than that of the other, it follows that the circumference muft be lefs than $3\frac{1}{7}$ times the diameter, but greater than $3\frac{10}{71}$ times; fo that, taking the firft of thefe limits as being expreffed by the fmalleft numbers, the circumference will be to the diameter as $3\frac{1}{7}$ to 1, or as 22 to 7 nearly.

Although the approximate ratio inveftigated by Archimedes be the oldeft known to have been found in the weftern world, yet one more accurate feems to have been known at a much earlier period in India. This we learn from the *Inftitutes of Akbar (Ayeen Akberry)* where it is faid that the Hindoos fuppofe the diameter of a circle to be to its circumference as 1250 to 3927. Now this ratio, which is the fame as that of 1 to 3.1416, when found in the fimpleft and moft elementary manner muft have required the infcription of a polygon of 768 fides in the circle, and muft have been attended with nine extractions of the fquare root, each carried as far as ten places of figures.

We learn from Simplicius that Nicomedes and Apollonius both attempted to fquare the circle, the former by means of a curve which he called the *Quadratrix*; the invention of which, however, is afcribed to Dinoftratus, and the latter alfo by the help of a curve denominated the fifter to the tortuous line or *fpiral*, and which was probably no other than the quadratrix of Dinoftratus; the nature of which, and the manner of its application to the fubject in queftion, we fhall briefly explain.

Fig. 2. Let AFB be a quadrant of a circle (fig. 2.) and C its centre; and conceive the radius CF to revolve uniformly about C from the pofition CA until at laft it coincide with CB; while at the fame time a line DG is carried with an uniform motion from A towards CB; the former line continuing always parallel to the latter, until at laft they coincide; both motions being fuppofed to begin and end at the fame inftant. Then the point E in which the revolving radius CF and the moveable line DG interfect one another will generate a certain curve line AEH, which is the *Quadratrix* of Dinoftratus.

Draw EK,FL both perpendicular to CB; then becaufe the radius AC and the quadrantal arch AFB are uniformly generated in the fame time by the points D and F, the contemporaneous fpaces defcribed will have to one another the fame ratio as the whole fpaces; that is, AD : AF : : AC : AB; hence we have AC : AB : : DC, or EK : FB. Now as the moveable point F approaches to B, the ratio of the ftraight line EK to the arch FB will approach to, and will manifeftly be ultimately the fame as the ratio of the ftraight line EK to the ftraight line FL, which again is equal to the ratio of CE to CF; therefore the ratio of the radius AC to the quadrantal arch AFB is the limit of the ratio of CE to CF, and confequently equal to the ratio of CH to CB, H being the point in which the quadratrix meets CB. Since therefore CH : CB : : CA or CB : quad. arch AFB, if by any means we could determine the point H, we might then find a ftraight line equal to the quadrantal arch, (by finding a third proportional to CH and CB) and confequently a ftraight line equal to the circumference. The point H, however, cannot be determined by a geometrical conftruction, and therefore all the ingenuity evinced by the perfon who firft thought of this method of rectifying the circle (which certainly is confiderable) has been unavailing.

The Arabs, who fucceeded the Greeks in the cultivation of the fciences, would no doubt have their pretended fquarers of the circle. We however know nothing more than that fome one of them believed he had difcovered that the diameter being unity, the circumference was the fquare root of 10; a very grofs miftake; for the fquare root of 10 exceeds 3.162; but Archimedes had demonftrated that the circumference was lefs than 3.143.

It appears that, even during the dark ages, fome attempts were made at the refolution of this famous problem, which however have always remained in manufcripts buried in the duft of old libraries. But upon the revival of learning the problem was again agitated by different writers, and particularly by the celebrated Cardinal De Cufa, who diftinguifhed himfelf by his unfortunate attempt to refolve it. His mode of inveftigation, which had no folid foundation in geometry, led him to conclude, that if a line equal to the fum of the radius of a circle and the fide of its infcribed fquare were made the diameter of another circle, and an equilateral triangle were infcribed in this laft, the perimeter of this triangle would be equal to the circumference of the other circle. This pretended quadrature of the cardinal's was refuted by Regiomontanus; and indeed the tafk was not difficult; for, according to his conftruction, the diameter being 1, the circumference was greater than $3\frac{1}{7}$; a conclufion which muft be abfurd, feeing that Archimedes had demonftrated that it muft be lefs than that number.

It would be trefpaffing too much upon the patience of our readers, were we to mention all the abfurd and erroneous attempts which have been made during the laft three centuries to fquare the circle. In a fupplement to Montucla's excellent work, *Hiftoire des Mathematiques*, we find upwards of forty pretenders to the honour of this difcovery enumerated. Thefe were almoft all very ignorant of geometry; and many of them were wild vifionaries, pretending to difcover inexplicable relations between the plain truths of mathematics and the moft myfterious doctrines of religion. If thofe who have fought the quadrature of the circle had been previoufly initiated in the doctrines of geometry, although they miffed attaining the object they had in view, yet they could not have failed to have extended the boundaries of the fcience by the difcovery of many new propofitions. From fuch perfons, however, as have generally purfued this inquiry, no improvement whatever of the fcience was to be expected; although, indeed, in fome inftances, it has derived advantage from the labours of fuch as have undertaken to expofe the abfurdity of their conclufions; as in the cafe of Metius, who in refuting the quadrature of one *Simon à Quercu*, found a much nearer approximation to the ratio of the diameter to the circumference than had been previoufly known, at leaft in Europe, viz. that of 113 to 355, which reduced to decimals is the fame as the ratio of 1 to 3.1415929, differing from the truth only in the feventh place of decimals.

Among the moft remarkable of thofe who have recorded their own folly by publifhing erroneous refolutions of the problem, we may reckon the celebrated Jofeph Scaliger. Full of felf-conceit, he believed that, entering

tering upon the ſtudy of geometry, he could not fail to ſurmount by the force of his genius thoſe obſtacles which had completely ſtopt the progreſs of all preceding inquirers. He gave the reſult of his meditations to the world in 1592, under the title *Nova Cyclometria ;* but he was refuted by Clavius, by Vieta, and others, who ſhewed that the magnitude he had aſſigned to the circumference was a little *leſs* than the perimeter of the inſcribed polygon of 192 ſides, which proved beyond a doubt that he was wrong. Scaliger, however, was not to be convinced of the abſurdity of his concluſion ; and indeed, in almoſt every inſtance, pretenders to this diſcovery have not been more remarkable for their folly in committing abſurd blunders, than for their obſtinacy in maintaining that they were in the right, and all who held a contrary opinion in an error.

The famous Hobbes came alſo upon the field about the year 1650, with pretenſions not only to the quadrature of the circle, but alſo to the triſection of an angle, the rectification of the parabola, &c. ; but his pretended ſolutions were refuted by Dr Wallis. And this circumſtance afforded him occaſion to write not only againſt geometers, but even againſt the ſcience of geometry itſelf.

We find it recorded by *Montucla*, as a ſort of phenomenon, that one Richard White, an Engliſh Jeſuit, having happened upon what he conceived to be a quadrature of the circle, which he publiſhed under the title, *Chryſaeſpis ſeu Quadratura Circuli*, ſuffered himſelf at laſt to be convinced by ſome of his friends that he was wrong both in his quadrature of the circle, and in his rectification of the ſpiral. But a ſolution of the ſame problem found out by one Mathulen of Lyons, did not produce in the end ſo much advantage to its author. This man in 1728 announced to the learned world that he had diſcovered both the quadrature of the circle and a perpetual motion ; and he was ſo certain of the truth of theſe diſcoveries, that he conſigned 1000 *ecus* (about 125l.) to be paid to any one who ſhould demonſtrate that he was deceived in either. The taſk was not difficult. Nicole of the Academy of Sciences demonſtrated that he was wrong, and he himſelf allowed it ; but he heſitated to pay the money, which Nicole had relinquiſhed in favour of the *Hotel Dieu* of Lyons. The affair went before a court of juſtice, which adjudged the money to be paid, as Nicole had deſtined it, to the poor. At a later period, viz. in 1753, the Chevalier de Cauſans, a French officer, and a man who was never expected to be a mathematician, ſuddenly found a quadrature of the circle in procuring a circular piece of turf to be cut ; and riſing from one truth to another, he explained by his quadrature the doctrine of original ſin, and the Trinity. He engaged himſelf by a public writing to depoſit with a notary the ſum of 300,000 francs, to be wagered againſt ſuch as ſhould oppoſe him, and he actually lodged 10,000, which were to devolve to him who ſhould demonſtrate his error. This was eaſily done, as it reſulted from his diſcovery that a circle was equal to its circumſcribing ſquare, that is, a part to the whole ! Some perſons came forward to anſwer his challenge, and in particular a young lady ſued him at one of the courts of law ; but the French king judged that the Chevalier's fortune ought not to ſuffer on account of his whim ; for, ſetting aſide this piece of folly, in every other reſpect he was a worthy man. The procedure was therefore ſtopt, and the wager declared void.

We ſhall not enter farther into the hiſtory of theſe vain and abſurd attempts to reſolve this important problem, but proceed to ſtate what has actually been done by men of ſound minds and real mathematical acquirements towards its ſolution. And in the firſt place it may be obſerved that the problem admits of being propoſed under two different forms : for it may be required to find either the area of the whole circle, or, which is the ſame thing, the length of the whole circumference ; or elſe to find the area of any propoſed ſector or ſegment, or, which is equivalent, the length of the arch of the ſector or ſegment. The former is termed the *definite* and the latter the *indefinite* quadrature of the circle. The latter evidently is more general than the former, and includes it as a particular caſe. Now if we could find by any means a finite algebraic equation that ſhould expreſs the relation between any propoſed arch of a circle, and ſome known ſtraight line, or lines, the magnitude of one or more of which depended on that arch, then we would have an abſolute rectification of the arch, and conſequently a rectification or quadrature alſo of the whole circle. We here ſpeak of an analytical ſolution of the problem ; the ancients, however, who were almoſt entirely ignorant of this branch of mathematical ſcience, muſt have endeavoured to treat it entirely upon geometrical principles. It is now well known, however, that all geometrical problems may be ſubjected to analyſis ; and that it is only by ſuch a mode of proceeding they have in many caſes been reſolved.

With reſpect to the definite quadrature of the circle, it is commonly underſtood that no unexceptionable demonſtration of its impoſſibility has hitherto been publiſhed. It is true that James Gregory, in his *vera circuli et Hyperbolæ quadratura*, has given what he conſidered as ſuch a demonſtration ; but it has been objected to, particularly by Huygens, one of the beſt geometers of his time. We are, however, certain that the ratio of the diameter to the circumference, as alſo, that the ratio of the ſquare of the diameter to the ſquare of a ſtraight line equal to the circumference, cannot be expreſſed by rational numbers, for this has been ſtrictly demonſtrated by Lambert in the Berlin Memoirs for 1761. A demonſtration is alſo given in Legendre's *Geometrie*. As to the indefinite quadrature, if Newton's demonſtration of the 28th lemma of the firſt book of his *Principia* be correct, the thing ought to be abſolutely impoſſible. For the object of that propoſition is to prove that in no oval figure whatever, that returns into itſelf, can the area cut off by ſtraight lines at pleaſure be univerſally found by an equation of a finite dimenſion, and compoſed of a finite number of terms. If this be true, then it will be impoſſible to expreſs any ſector of a circle taken at pleaſure in finite terms. It is however to be remarked, that the accuracy of the reaſoning by which Newton has attempted to eſtabliſh the truth of the general propoſition has been queſtioned by no leſs a geometer than D'Alembert ; and indeed we know one oval curve, which returns into itſelf, and which according to Newton's propoſition ought therefore not to admit of an indefinite quadrature ; yet this is by no means the caſe, for it does really admit of ſuch a quadrature. The curve we mean is the *lemniſcata*, the equation of which is $(x^2+y^2)^2=a^2(x^2-y^2)$, where x and y denote its coordinates,

ordinates, and a is put for a given line. The figure of the curve is nearly that of the numeral character 8. Upon the whole then we may infer that an unexceptionable demonftration of the impoffibility of expreffing either the whole circle, or any propofed fector of it, by a finite equation, is ftill among the *defiderata* of mathematics.

We come now to fpeak of the different methods which have been found for approximating to the area or to the circumference. We have already noticed the approximation to the ratio of the diameter to the circumference found by Archimedes, and the earlier and more accurate approximation of the Indian mathematicians. Archimedes's ratio is the only one found by the ancients in the weftern world that has defcended to modern times, and it appears to have been the moft accurate known, until about the year 1585, when Metius, in refuting a pretended quadrature, found the more accurate ratio of 113 to 355, as we have already noticed. About the fame time Vieta, and Adrianus Romanus publifhed their ratios expreffed in decimals, the former carrying the approximation to ten decimals inftead of fix, (which was the number of accurate figures expreffed by Metius's ratio), and the latter extending it to 17 figures. Vieta alfo gave a kind of feries, which being continued to infinity, gave the value of the circle.

Thefe approximations, however, were far exceeded by that of Ludolph Van Ceulen, who in a work publifhed in Dutch in 1610, carried it as far as 36 figures, fhowing that if the diameter were unity, the circumference would be greater than 3.14159,26535,89793, 23846,26433,83279,50288, but lefs than the fame number with the laft figure increafed by an unit. This work was tranflated into Latin by Snellius, and publifhed under the title, *De Circulo et Adfcriptis*. In finding this approximation, Van Ceulen followed the method of Archimedes, doubling continually the number of fides of the infcribed and circumfcribed polygons, until at length he found two which differed only by an unit in the 36th place of decimals in the numbers expreffing their perimeters. This, however, muft have been rather a work of patience than of genius; and indeed the labour muft have been prodigious. He feems to have valued highly this fingular effort, for in imitation of Archimedes, whofe tomb was adorned with a fphere and cylinder, in commemoration of his difcovery of the proportion which thefe folids bear to one another, he requefted that the ratio he had found might be infcribed on his tomb, which was accordingly done.

Snellius found means to abridge greatly the labour of calculation by fome very ingenious theorems; and although he did not go beyond Van Ceulen, yet he verified his refult. His difcoveries on this fubject are contained in a work called *Willebrordi Snellii Cyclometricus de Circuli Dimenfione*, &c. *Lugd. Bat.* 1621.

Defcartes found alfo a geometrical conftruction, which being repeated continually, gave the circumference, and from which he might eafily have deduced an expreffion in the form of a feries.

Gregory of St Vincent diftinguifhed himfelf alfo on this fubject. It is true he committed a great error in fuppofing he had difcovered the quadrature of both the circle and hyperbola; but he had previoufly made fo many beautiful geometrical difcoveries, deduced with much elegance after the manner of the ancients, that it would be wrong to number him with thofe abfurd pretenders which we have already noticed. Gregory's miftake was the caufe of a fharp controverfy carried on between his difciples on the one fide, and by Huygens, Merfennus and Leftaud on the other; and it was this that gave Huygens occafion to confider particularly the quadrature of the circle, and to inveftigate various new and curious theorems relating to it, which are contained in his *Theoremata de Quadratura Hyperboles, Ellipfis et Circuli*, 1651; and in his work *De Circuli Magnitudine Inventa*, 1654. In particular he fhowed, that if c denote the chord of an arch, and s its fine, then the arch itfelf will be greater than $c+\frac{1}{3}(c-s)$, but lefs than $c+\frac{4c+s}{2c+3s}\times\frac{1}{3}(c-s)$: he alfo fhowed that the arch is lefs than the fum of $\frac{2}{3}$ of its fine and $\frac{1}{3}$ of its tangent. Thefe theorems greatly fhorten the labour of approximating to the ratio of the diameter to the circumference, by means of infcribed and circumfcribed figures, infomuch that by the infcribed polygons of 6 and 12 fides, we may obtain it to the fame degree of accuracy as Archimedes did by the infcribed and circumfcribed polygons of 96 fides.

James Gregory, in his *Vera Circuli et Hyperbolæ Quadratura*, gave feveral curious theorems upon the relation of the circle to its infcribed and circumfcribed polygons, and their ratios to one another; and by means of thefe he found with infinitely lefs trouble than by the ordinary methods, and even by thofe of Snellius, the meafure of the circle as far as 20 places of figures. He gave alfo, after the example of Huygens, conftructions for finding ftraight lines nearly equal to arches of a circle, and of which the degree of accuracy was greater. For example, he found that if A be put for the chord of an arch of a circle, and B for twice the chord of half the arch, and C be taken fuch that A+B : B : : 2 B : C, then the arch itfelf is nearly equal to $\frac{8C+8B-A}{15}$, but a little lefs, the error in the cafe of a complete femicircle being lefs than its $\frac{1}{3500}$ part; and when the arch does not exceed 120°, it is lefs than its $\frac{1}{40000}$ part; and finally, for a quadrant the error is not greater than its $\frac{1}{300000}$ part. And farther, that if D be fuch that A : B : : B : D, then the arch is nearly equal to $\frac{12C+4B-D}{15}$, but a little greater, the error in the femicircle being lefs than its $\frac{1}{1000}$ part, and in a quadrant lefs than its $\frac{1}{60000}$ part.

The difcoveries of Dr Wallis, delivered in his *Arithmetica Infinitorum* publifhed in 1655, led him to a fingular expreffion for the ratio of the circle to the fquare of its diameter. He found that the former was to the latter as 1 to the product

$$\frac{3\times3\times5\times5\times7\times7\times9\times9\times11\times11\ \&c.}{2\times4\times4\times6\times6\times8\times8\times10\times10\times12}$$

the fractions $\frac{1}{2}$, $\frac{1}{4}$, $\frac{5}{4}$, $\frac{5}{6}$, &c. being fuppofed infinite in number. The products being fuppofed continued to infinity, we have the ratio exactly; but if we ftop at any finite number of terms, as muft neceffarily be the cafe in its application, the refult will be alternately too great and too fmall, according as we take an odd or an even number of terms of the numerator and denominator.

Thus

Thus the fraction $\frac{3}{2}$ is too great; on the other hand, $\frac{3\times 3}{2\times 4}=\frac{9}{8}$ is too small, and $\frac{3\times 3\times 5}{2\times 4\times 4}=\frac{45}{32}$ too great, and so on. But to approach as near as possible in each case, Wallis directs to multiply the product by the square root of a fraction formed by adding to unity the reciprocal of the last factor in either its numerator or denominator; then the result, although much nearer, will be too great if the number whose reciprocal is taken be the last in the numerator, but too small if it be the number in the denominator. Thus the following series of expressions will give approximate values of the infinite product $\frac{3\times 3\times 5\times 5\times 7\times 7\ \&c.}{2\times 4\times 4\times 6\times 6\times 8\times 8}$ which are alternately too great and too small.

$$\frac{3\cdot 3\cdot 5\cdot 5}{2.4.4.6}\sqrt{(1+\tfrac{1}{5})};\ \frac{3\cdot 3\cdot 5\cdot 5}{2.4.4.6}\sqrt{(1+\tfrac{1}{6})};$$

$$\frac{3\cdot 3\cdot 5\cdot 5\cdot 7\cdot 7}{2.4.4.6.6.8}\sqrt{1+\tfrac{1}{7})};\ \frac{3\cdot 3\cdot 5\cdot 5\cdot 7\cdot 7}{2.4.4.6.6.8}\sqrt{(1+\tfrac{1}{8})};\ \&c.$$

these values, alternately too great and too small, fall between the known limits.

An expression of another kind for the ratio of the circle to the square of the diameter was found by Lord Brounker. He showed that the circle being unity, the square of the diameter is expressed by the continued fraction

$$1+\cfrac{1}{2+\cfrac{9}{2+\cfrac{25}{2+\cfrac{49}{2+,\&c.}}}}$$

which is supposed to go on to infinity, the numerators 1, 9, 25, 49, &c. being the squares of the odd numbers 1, 3, 5, 7, &c. By taking two, three, four, &c. terms of this fraction, we shall have a series of approximate values which are alternately greater and less than its accurate value.

Such were the chief discoveries relating to the quadrature of the circle made before the time of Newton: many others, however, were quickly added by that truly great man, as well as by his contemporaries. In particular, Newton himself showed that if s denote the sine, and v the versed sine of an arch, then the radius being unity, the arch is equal to either of the following series,

$$s+\frac{1.s^3}{2.3}+\frac{1.3\,s^5}{2.4.5}+\frac{1.3.5\,s^7}{2.4.6.7}+\frac{1.3.5.7\,s^9}{2.4.6.8.9}+\ \&c.$$

$$\sqrt{2v}\times\left(1+\frac{1.v}{2.3.2}+\frac{1.3\,v^2}{2.4.5.2^2}+\frac{1.3.5\,v^3}{2.4.6.7.2^3}+\frac{1.3.5\,7\,v^4}{2\,4.6.8.9.2^4}+\ \&c.\right)$$

And James Gregory found that t being put for the tangent, the arch is expressed by the very simple series

$$t-\frac{t^3}{3}+\frac{t^5}{5}-\frac{t^7}{7}+\frac{t^9}{9}-\ \&c.$$

We have investigated the first of these series at § 140, and the third at § 137, of the article FLUXIONS: the second is easily obtained from the first by considering that since the sine of an arch is half the chord of twice the arch, that is, half of a mean proportional between the diameter and versed sine of twice the arch; we have therefore only to multiply the first series by 2, and to substitute $\frac{1}{2}\sqrt{2v}$ instead of s, and we get the second series.

By taking $s=\frac{1}{2}$, then, because in this case the arch contains 30°, we have half the circumference to the radius 1, or the whole circumference to the diameter 1, expressed by the infinite series

$$3\ (1+\frac{1}{2.3.2^2}+\frac{1.3}{2.4.5.2^4}+\frac{1.3.5}{2.4.6.7.2^6}+\frac{1.3.5.7}{2.4.6.8.9.2^8}+\ \&c.)$$

And by supposing that in the third series $t=1$, in which case the arch is one-eighth of the circumference, we have the same things expressed by the series

$$4\ (1-\frac{1}{3}+\frac{1}{5}-\frac{1}{7}+\frac{1}{9}-\frac{1}{11}+\ \&c.)$$

which was given by Leibnitz as a quadrature of the circle in the Leipsic Acts in the year 1682; but was discovered by him 1673. Gregory, however, had found the series under its general form several years before. By the first of these two numeral series we can readily compute the circumference of the circle to a tolerable degree of accuracy; but the second is altogether inapplicable in its present form on account of the slowness of its convergency; for Newton has observed that to exhibit its value exact to twenty places of figures, there would be occasion for no less than five thousand millions of its terms, to compute which would take up above a thousand years.

The slowness of the convergency has arisen from our supposing $t=1$. If we had supposed t greater than 1, then the series would not have converged at all, but on the contrary diverged. But by giving to t a value less than 1, then the rate of convergency will be increased, and that so much the more, as t is smaller.

If we suppose the arch of which t is the tangent to be 30°, then t will be $\sqrt{\frac{1}{3}}=\frac{1}{3}\sqrt{3}$, and therefore half the circumference to radius unity, or the circumference to the diameter unity, which in this case is $6t\ (1-\frac{t^2}{3}+\frac{t^4}{5}-\frac{t^6}{7}+\frac{t^8}{9}-\ \&c.)$ will be

$$\sqrt{12}\ (1-\frac{1}{3\cdot 3}+\frac{1}{5\cdot 3^2}-\frac{1}{7\cdot 3^3}+\frac{1}{9\cdot 3^4}-\ \&c.).$$

By means of this series, in an hour's time the circumference may be found to be nearly 3.141592653590, which is true to 11 decimal places, and is a very considerable degree of accuracy, considering the smallness of the labour. But Mr Machin, enticed by the easiness of the process, was induced, about the beginning of the last century, to continue the approximation as far as 100 places of figures, thus finding the diameter to be to the circumference as 1 to 3.14159.26535,89793, 23846,26433.83279,50288,41971,69399,37510,58209 74944,59230,78164,06286,20899,86280,34825,34211 70680. After him, De Lagny continued it as far as 128

Squaring.

128 figures. But he has alſo been outdone; for in Radcliffe's library at Oxford, there is a manuſcript in which it is carried as far as 150 figures!

Although this laſt ſeries, which was firſt propoſed by Dr Halley, gives the ratio of the diameter to the circumference with wonderful facility when compared with the operoſe method employed by Van Ceulen, yet others have been ſince found which accompliſh it with ſtill greater eaſe. In Halley's ſeries we have to compute the irrational quantity $\sqrt{12}$, becauſe of the irrational value which it was neceſſary to give to t in order to render it ſufficiently ſmall, and at the ſame time an exact part of the whole circumference; but Mr Machin contrived, by a very ingenious artifice, to reduce the computation of an arch of 45°, and conſequently the length of the whole circumference, to two ſeries which contain only rational quantities, and which at the ſame time converge with great rapidity. The nature of this artifice, and the manner in which it occurred to its author, is explained by Dr Hutton in his very excellent treatiſe on Menſuration, as follows: "Since the chief advantage (in the application of Gregory's ſeries to the rectification of the circle) conſiſts in taking ſmall arches, whoſe tangents ſhall be numbers eaſy to manage, Mr Machin very properly conſidered, that ſince the tangent of 45° is 1, and that the tangent of any arch being given, the tangent of the double of that arch can eaſily be had; if there be aſſumed ſome ſmall ſimple number as the tangent of an arch, and then the tangent of the double arch be continually taken, until a tangent be found nearly equal to 1, which is the tangent of 45°, by taking the tangent anſwering to the ſmall difference of 45° and this multiple, there would be found two very ſmall tangents, viz. the tangent firſt aſſumed, and the tangent of the difference between 45° and the multiple arch; and that therefore the lengths of the arches correſponding to theſe two tangents being calculated, and the arch belonging to the tangent firſt aſſumed being ſo often doubled as the multiple directs, the reſult, increaſed or diminiſhed by the other arch, according as the multiple ſhould be below or above it, would be the arch of 45°.

"Having thus thought of his method, by a few trials he was lucky enough to find a number (and perhaps the only one) proper for his purpoſe; viz. knowing that the tangent of $\frac{1}{4}$ of 45° is nearly $=\frac{1}{5}$, he aſſumed $\frac{1}{5}$ as the tangent of an arch. Then, ſince if t be the tangent of an arch, the tangent of the double arch will be $\frac{2t}{1-t^2}$, the radius being 1; the tangent of the double arch to that of which $\frac{1}{5}$ is the tangent will $\frac{5}{12}$, and the tangent of the double of this arch will be $\frac{120}{119}$, which being very nearly equal to 1, ſhews, that the arch which is equal to four times the firſt arch is very near 45°. Then, ſince the tangent of the difference between an arch of 45°, and an arch greater than 45°, whoſe tangent is T, is $\frac{T-1}{T+1}$, we ſhall have the tangent of the difference between 45°, and the arch whoſe tangent is $\frac{120}{119}$ equal to $\frac{1}{239}$. Now, by calculating from the general ſeries the arches whoſe tangents are $\frac{1}{5}$ and $\frac{1}{239}$, (which may be quickly done by reaſon of the ſmallneſs and ſimplicity of the numbers), and taking the latter arch from four times the former, the remainder will be the arch of 45°."

If we ſubſtitute $\frac{1}{5}$ inſtead of t in the general ſeries, we ſhall have the arch whoſe tangent is $\frac{1}{5}$ expreſſed by the ſeries $\frac{1}{5}-\frac{1}{3\cdot 5^3}+\frac{1}{5\cdot 5^5}-\frac{1}{7\cdot 5^7}+$, &c.; and, in like manner, by ſubſtituting $\frac{1}{239}$ for t, we get the arch whoſe tangent is $\frac{1}{239}$ expreſſed by the ſeries $\frac{1}{239}-\frac{1}{3\cdot 239^3}+\frac{1}{5\cdot 239^5}-\frac{1}{7\cdot 239^7}+$, &c. Now, ſince four times the arch to tan. $\frac{1}{5}$ diminiſhed by the arch to tan. $\frac{1}{239}$ is equal to the arch to tan. 1, that is, to the arch of 45°, or $\frac{1}{4}$ of the ſemicircumference; therefore, half the circumference of a circle to rad. $=1$, or the whole circumference, the diameter being 1, is equal to

$$16\left(\frac{1}{5}-\frac{1}{3\cdot 5^3}+\frac{1}{5\cdot 5^5}-\frac{1}{7\cdot 5^7}+\frac{1}{9\cdot 5^9}-, \text{\&c.}\right)$$
$$-4\left(\frac{1}{239}-\frac{1}{3\cdot 239^3}+\frac{1}{5\cdot 239^5}-\frac{1}{7\cdot 239^7}+\frac{1}{9\cdot 239^9}-, \text{\&c.}\right)$$

and this is Machin's ſeries for the rectification of the circle.

The happy idea which Machin had conceived of reducing the rectification of the arch whoſe tangent is unity to that of two arches whoſe tangents are ſmall rational fractions, having each unity for a numerator, appears alſo to have occurred to Euler; and the ſame thought has, ſince his time, been purſued by other mathematicians, who have contrived to reſolve an arch of 45° into three or more ſuch arches. We ſhall ſhew how this may be done, beginning with the inveſtigation of the following problem.

Problem. Suppoſing n, x, and y, to denote three whole numbers, ſuch, that the arch whoſe tangent is $\frac{1}{n}$ is equal to the ſum of two arches whoſe tangents are $\frac{1}{x}$ and $\frac{1}{y}$, radius being unity, it is required to determine all poſſible values of the numbers x and y in terms of the number n.

Solution. It is manifeſt from the formula for the tangent of the ſum of two arches (Algebra, § 368.) that $\frac{1}{n}=\frac{\frac{1}{x}+\frac{1}{y}}{1-\frac{1}{xy}}$; hence we have $\frac{1}{n}=\frac{x+y}{xy-1}$, and $nx+ny=xy-1$, and $y(x-n)=nx+1$; and, laſtly, $y=\frac{nx+1}{x-n}=n+\frac{n^2+1}{x-n}$. Now, as by hypotheſis, y is a whole number, it is manifeſt that $\frac{n^2+1}{x-n}$ muſt be a whole number; therefore, $x-n$ muſt be a diviſor of n^2+1. Let p be any diviſor of n^2+1, and q the quotient, that is, let $pq=n^2+1$, then $x-n=p$, and $x=n+p$: And ſince $\frac{n^2+1}{x-n}=\frac{pq}{p}=q$, therefore $y=n+q$; thus the values of x and y are determined in terms of n as required; and by giving to p and q all poſſible values, we ſhall have all the values of x and y that can exist. This solution affords us the following theorem.

THEOREM. Let n denote any whole number, and let n^2+1 be resolved into any two factors p and q, (one of which may be unity), that is, let $pq=n^2+1$; the arch whose tangent is $\frac{1}{n}$ is equal to the sum of the arches whose tangents are $\frac{1}{n+p}$, and $\frac{1}{n+q}$ respectively.

For the sake of brevity, let $A\frac{1}{n}$ be put to denote the arch, having for its tangent $\frac{1}{n}$; then, according to this notation, our theorem will be expressed thus, $A\frac{1}{n}= A\frac{1}{n+p}+A\frac{1}{n+q}$. Let us now suppose $n=1$, then $n^2+1=2=1\times 2$, therefore, the only values which we can give in this case to p and q are $p=1$, $q=2$, and these being substituted, we have

$$A\,1=A\tfrac{1}{2}+A\tfrac{1}{3}.$$

From which it appears, that the arch whose tangent is unity (that is, $\frac{1}{8}$ of the circumference), is the sum of the arches whose tangents are $\frac{1}{2}$ and $\frac{1}{3}$. This is Euler's theorem, and by means of it, putting $\frac{1}{2}$ and $\frac{1}{3}$ for t in the general series $t-\frac{1}{3}t^3+\frac{1}{5}t^5-\frac{1}{7}t^7+$, &c. we get half the circumference to radius 1 equal to

$$4\left\{\begin{array}{l}\frac{1}{2}-\frac{1}{3\cdot 2^3}+\frac{1}{5\cdot 2^5}-\frac{1}{7\cdot 2^7}+\frac{1}{9\cdot 2^9}-\text{, \&c.}\\ +\frac{1}{3}-\frac{1}{3\cdot 3^3}+\frac{1}{5\cdot 3^5}-\frac{1}{7\cdot 3^7}+\frac{1}{9\cdot 3^9}-\text{, \&c.}\end{array}\right\}$$

Let us now suppose $n=2$, then $n^2+1=5=1\times 5$, hence the only values which p and q can have are 1 and 5; and in this case our general formula gives $A\frac{1}{2}=A\frac{1}{3}+A\frac{1}{7}$.

If now from the two equations

$$A\,1=A\tfrac{1}{2}+A\tfrac{1}{3};\qquad A\tfrac{1}{2}=A\tfrac{1}{3},+A\tfrac{1}{7},$$

we eliminate successively $A\frac{1}{2}$ and $A\frac{1}{3}$, we shall obtain the two following:

$$A\,1=2\,A\tfrac{1}{3}+A\tfrac{1}{7};\qquad A\,1=2\,A\tfrac{1}{2}-A\tfrac{1}{7}.$$

From the first of these it appears that $\frac{1}{8}$ of the circumference is equal to the sum of twice the arch to tan. $\frac{1}{3}$, and once the arch to tan. $\frac{1}{7}$; and from the second, that the same quantity is equal to the excess of twice the arch to tan. $\frac{1}{2}$ above the arch to tan. $\frac{1}{7}$; and from each of these, an expression for the whole circumference may be obtained analogous to that which we have found above from Euler's formula, but which will converge faster, and therefore is better.

The resolution of an arch of 45° into three other arches, may be effected by means of our general formula, as follows: Put $n=3$, then $n^2+1=10=1\times 10=2\times 5$, hence we have $p=1$, and $q=10$, and also $p=2$, and $q=5$; therefore, substituting, we get two different values of $A\frac{1}{3}$, viz.

$$A\tfrac{1}{3}=A\tfrac{1}{4}+A\tfrac{1}{13};\qquad A\tfrac{1}{3}=A\tfrac{1}{5}+A\tfrac{1}{8}.$$

From these, and the equation $A\,1=2\,A\frac{1}{3}+A\frac{1}{7}$, we get, by exterminating $A\frac{1}{3}$, the two following expressions for $A\,1$, an arch of 45°.

$$A\,1=2\,A\tfrac{1}{4}+A\tfrac{1}{7}+2\,A\tfrac{1}{13};\quad A\,1=2\,A\tfrac{1}{5}+A\tfrac{1}{7}+2A\tfrac{1}{8}.$$

These give each an expression for the circumference composed of three series. The labour, however, of computing by either of them, particularly the latter, will probably be less than by any of the formulas composed of two series, on account of the greater degree of quickness with which the series will converge. All the preceding formulas have been investigated in different ways by different mathematicians. That, however, which we are about to investigate, we believe is new. Let n in the general formula be taken equal to 5; then $n^2+1=26=1\times 26=2\times 13$, therefore $p=1$, $q=26$, also $p=2$, $q=13$, hence we find $A\frac{1}{5}=A\frac{1}{6}+A\frac{1}{31}$, and also $A\frac{1}{5}=A\frac{1}{7}+A\frac{1}{18}$. From this last equation, and the equation $A\,1=2\,A\frac{1}{5}+A\frac{1}{7}+2\,A\frac{1}{8}$, let $A\frac{1}{5}$ be eliminated, and the result is

$$A\,1=3\,A\tfrac{1}{7}+2\,A\tfrac{1}{8}+2\,A\tfrac{1}{18}.$$

This appears to be the most convenient expression of any we have yet found, because the fractions are smaller, while at the same time two of the denominators consist of only one figure, and the third, which consists of two, admits of being resolved into factors. By the same mode of reasoning we have found this expression

$$A1=2A\tfrac{1}{8}+3A\tfrac{1}{9}+2A\tfrac{1}{18}+3A\tfrac{1}{32},$$

which consists of four terms; but for the sake of brevity we omit its investigation.

We shall now apply the formula $A1=3A\frac{1}{7}+2A\frac{1}{8}+2A\frac{1}{18}$ to the actual calculation of the arch of 45°, the radius of the circle being unity.

I. Calculation of the length of the arch whose tangent is $\frac{1}{7}$.

In this case, because $t=\frac{1}{7}$, we have

$$A\frac{1}{7}=\frac{1}{7}-\frac{1}{3\cdot 7^3}+\frac{1}{5\cdot 7^5}-\frac{1}{7\cdot 7^7}+\frac{1}{9\cdot 7^9}-\text{, \&c.}$$

$\frac{1}{7}$ =.1428571428571	$\frac{1}{3\cdot 7^3}$=.0009718172983
$\frac{1}{5\cdot 7^5}$=.0000118998037	$\frac{1}{7\cdot 7^7}$=.0000001734665
$\frac{1}{9\cdot 7^9}$=.0000000027534	$\frac{1}{11\cdot 7^{11}}$=.0000000000460
$\frac{1}{13\cdot 7^{13}}$=.0000000000008	.0009719908108

+.1428690454150 amount of positive terms.
—.0009719908108 amount of negative terms.

$A\frac{1}{7}$=.1418970546042

II. Calculation of the length of the arch whose tangent is $\frac{1}{8}$.

Here $t=\frac{1}{8}$, therefore,

$$A\frac{1}{8}=\frac{1}{8}-\frac{1}{3\cdot 8^3}+\frac{1}{5\cdot 8^5}-\frac{1}{7\cdot 8^7}+\text{, \&c.}$$

$\frac{1}{8}$

Squaring.

$$\frac{1}{8} = .1250000000000 \qquad \frac{1}{3.8^3} = .0006510416667$$
$$\frac{1}{5.8^5} = .0000061035156 \qquad \frac{1}{7.8^7} = .0000000681196$$
$$\frac{1}{9.8^9} = .0000000008278 \qquad \frac{1}{11.8^{11}} = .0000000000106$$
$$\frac{1}{13.8^{13}} = .0000000000001 \qquad .0006511097969$$

$$+.1250061043435$$
$$-.0006511097969$$

$$A\frac{1}{8} = .1243549945466$$

III. Calculation of the arch whofe tangent is $\frac{1}{18}$.

Here $t = \frac{1}{18}$, therefore,

$$A\frac{1}{18} = \frac{1}{18} - \frac{1}{3.18^3} + \frac{1}{5.18^5} - \frac{1}{7.18^7} +, \&c.$$

$$\frac{1}{18} = .0555555555556 \qquad \frac{1}{3.18^3} = .0000571559214$$
$$\frac{1}{5.18^5} = .0000001058443 \qquad \frac{1}{7.18^7} = .0000000002333$$
$$\frac{1}{9.18^9} = .0000000000006 \qquad .0000571561547$$

$$+.0555556614005$$
$$-.0000571561547$$

$$A\frac{1}{18} = .0554985052458$$

$$3A\tfrac{1}{7} = .4256911638126$$
$$2A\tfrac{1}{8} = .2487099890932$$
$$2A\tfrac{1}{18} = .1109970104916$$

$\frac{1}{8}$ of the circum. or $A1 = .785398163397$

Thus by a very eafy calculation we have obtained one-fourth of the circumference true to 12 decimal places; and indeed by this method we may find an approximate value of the ratio of the diameter to the circumference to 200 places of figures with, perhaps, as much eafe as Vieta or Romanus found it to 10 or 15 figures. We have already obferved that Van Ceulen defired that his quadrature, which extended only to 35 decimals, might be infcribed on his tomb; from which we may reafonably infer that the time and labour he had beftowed in the calculation muft have been very great; but by an artifice of the kind we have been explaining, Euler in 18 hours verified Lagny's quadrature of 128 figures.

In concluding this article we fhall briefly notice fome feries for the indefinite rectification of the circle, which have juft appeared in the fixth volume of the Edinburgh Philofophical Tranfactions. They are given by Mr W. Wallace of the Royal Military College, in a paper entitled, *New Series for the Quadrature of the Conic Sections, and the Computation of Logarithms*. Thefe feries do not give the arch directly, but only its reciprocal, or the powers of that reciprocal; it is however evident, that any one of thefe being known, the arch itfelf becomes immediately known. The firft feries is as follows. Let a denote any arch of a circle, and let its tangent, the tangents of its half, &c. be briefly denoted by tan. a, tan $\frac{1}{2}a$, &c. Then fhall

$$\frac{1}{a} = \frac{1}{\tan. a} + \tfrac{1}{2}\tan.\tfrac{1}{2}a + \tfrac{1}{4}\tan.\tfrac{1}{4}a + \tfrac{1}{8}\tan.\tfrac{1}{8}a.$$
$$+ \tfrac{1}{16}\tan.\tfrac{1}{16}a \ldots\ldots + T + T' + S.$$

Here the arches a, $\frac{1}{2}a$, $\frac{1}{4}a$, $\frac{1}{8}a$, &c. conftitute a geometrical progreffion, having the number of its terms infinite, and their common ratio $\frac{1}{2}$. The letters T and T′ are put for any two adjoining terms (after the firft) of the feries, and S is put for the fum of all the terms following thefe; and this fum is always contained between two limits, one of which is $\frac{1}{3}$ of the latter of the two terms T, T′, and the other is a third proportional to their difference; and the laft of the two being always lefs than the firft of thefe limits, but greater than the fecond. As a fpecimen of the way of applying this feries, we fhall give the calculation of the length of an arch of 90° to fix decimal places. In this cafe $\frac{1}{\tan. a}$ $=$ cotan. $a = 0$, tan. $\frac{1}{2}a = 1$, the remaining quantities tan. $\frac{1}{4}a$, tan. $\frac{1}{8}a$, &c. are to be computed from tan. $\frac{1}{2}a$ by this formula, tan. $\frac{1}{2}A = \sqrt{\left(\frac{1}{\tan.^2 A} + 1\right)} - \frac{1}{\tan. A}$.

Accordingly we find

$$\tan.\tfrac{1}{2}a = 1. \qquad \tan.\tfrac{1}{16}a = .0984914$$
$$\tan.\tfrac{1}{4}a = .4142136 \qquad \tan.\tfrac{1}{32}a = .0491268$$
$$\tan.\tfrac{1}{8}a = .1989123 \qquad \tan.\tfrac{1}{64}a = .0245486$$

$$\tfrac{1}{2}\tan.\tfrac{1}{2}a = .5000000$$
$$\tfrac{1}{4}\tan.\tfrac{1}{4}a = .1035534$$
$$\tfrac{1}{8}\tan.\tfrac{1}{8}a = .0248640$$
$$\tfrac{1}{16}\tan.\tfrac{1}{16}a = .0061557$$
$$T = \tfrac{1}{32}\tan.\tfrac{1}{32}a = .0015352$$
$$T' = \tfrac{1}{64}\tan.\tfrac{1}{64}a = .0003836$$
$$\left.\begin{array}{l} S < .0001278,7 \\ S > .0001277,7 \end{array}\right\} \text{Hence } S = .0001278$$

$$\frac{1}{a} = .6366197$$
Arch of $90° = a = 1.570796$.

The fecond feries given in this paper is expreffed as follows. Let cof. a, cof. $\frac{1}{2}a$, &c. denote the cofine of the arch, the cofine of its half, &c. Then

$$\frac{1}{a^2} = \frac{1}{4}\,\frac{1 + \text{cof. } a}{1 - \text{cof. } a} + \frac{1}{6}$$
$$-\left(\frac{1}{4^2}\,\frac{1 - \text{cof. }\frac{1}{2}a}{1 + \text{cof. }\frac{1}{2}a} + \frac{1}{4^3}\,\frac{1 - \text{cof. }\frac{1}{4}a}{1 + \text{cof. }\frac{1}{4}a}\right.$$
$$\left. + \frac{1}{4^4}\,\frac{1 - \text{cof. }\frac{1}{8}a}{1 + \text{cof. }\frac{1}{8}a} \ldots\ldots + T + T' + S\right)$$

Here, as before, the letters T, T′ denote any two adjacent terms of the feries in the parenthefis, and S is put for the fum of all the following terms, which in this cafe is always lefs than $\frac{1}{15}$T′, but greater than a third proportional to T—T′ and T′. This fecond feries converges

verges quicker than the firft, and is befides better adapted to calculation, becaufe the cofines of the feries of arches $\frac{1}{2}a$, $\frac{1}{4}a$, &c. are more eafily deduced from the cofine of a and one another than the tangents. The formula in this cafe being $\text{cof.} \frac{1}{2} A = \sqrt{\left(\frac{1+\text{cof. } A}{2}\right)}$.

There are various other feries for the rectification of any arch of a circle given in the fame paper, fome of which converge fafter than either of the two we have here fpecified, and all have the property of being applicable to every poffible cafe, and of having very fimple limits, between which the fum of all their terms following any propofed term are always contained. It may alfo be obferved that the principles from which they are deduced are of the moft fimple and elementary kind, infomuch that the author has ftated it as his opinion, that their inveftigation might even be admitted into and form a part of the elements of geometry.

STABBING, in *Law*. The offence of mortally ftabbing another, though done upon fudden provocation, is punifhed as murder; the benefit of clergy being taken away from it by ftatute. (See MURDER). For by Ja. I. c. 8. when one thrufts or ftabs another, not then having a weapon drawn, or who hath not then firft ftricken the party ftabbing, fo that he dies thereof within fix months after, the offender fhall not have the benefit of clergy, though he did it not of malice aforethought. This ftatute was made on account of the frequent quarrels and ftabbings with fhort daggers between the Scotch and the Englifh, at the acceffion of James I.; and being therefore of a temporary nature, ought to have expired with the mifchief which it meant to remedy. For, in point of folid and fubftantial juftice, it cannot be faid that the mode of killing, whether by ftabbing, ftrangling, or fhooting, can either extenuate or enhance the guilt; unlefs where, as in the cafe of poifoning, it carries with it internal evidence of cool and deliberate malice. But the benignity of the law hath conftrued the ftatute fo favourably in behalf of the fubject, and fo ftrictly when againft him, that the offence of ftabbing now ftands almoft upon the fame footing as it did at the common law. Thus, (not to repeat the cafes mentioned under MANSLAUGHTER, of ftabbing an adulterefs, &c. which are barely manflaughter, as at common law), in the conftruction of this ftatute it hath been doubted, whether, if the deceafed had ftruck at all before the mortal blow given, this does not take it out of the ftatute, though in the preceding quarrel the ftabber had given the firft blow; and it feems to be the better opinion, that this is not within the ftatute. Alfo it hath been refolved, that the killing a man, by throwing a hammer or other weapon, is not within the ftatute; and whether a fhot with a piftol be fo or not is doubted. But if the party flain had a cudgel in his hand, or had thrown a pot or a bottle, or difcharged a piftol at the party ftabbing, this is a fufficient reafon for having a weapon drawn on his fide within the words of the ftatute.

STACHYS, HEDGE-NETTLE, or ALL-HEAL, a genus of plants belonging to the clafs of didynamia, and order of gymnofpermia; and in the natural fyftem arranged under the 42d order, *Verticillatæ*. See BOTANY *Index*.

STADIUM, an ancient Greek long meafure, containing 125 geometrical paces, or 625 Roman feet, correfponding to our furlong. The word is faid to be formed from the Greek word στασις "a ftation," or ιστημι "to ftand," becaufe it is reported that Hercules having run a ftadium at one breath, ftood ftill at the end of it. The Greeks ufually meafured diftances by ftadia, which they called σταδιασμος. Stadium alfo fignified the courfe on which their races were run.

STADTHOLDER, formerly the principal magiftrate or governor of the Seven United Provinces. Although this office is now abolifhed by the ufurped influence of France, our readers will probably not be ill pleafed with a fhort account of the feveral powers and claims connected with it. To render that account the more intelligible, we fhall trace the office of a ftadtholder from its origin.

The Seven Provinces of the Low Countries were long governed by princes invefted with the fovereignty, though limited in their powers, and under various titles; as *Counts of Holland*, *Dukes of Guelder*, *Bifhop of Utrecht*, &c. When thefe countries fell to the princes of the houfe of Burgundy, and afterwards to thofe of Auftria, who had many other dominions, the abfence of the fovereign was fupplied by a ftadtholder or governor, vefted with very ample powers. Thefe ftadtholders or lieutenants had the adminiftration of the government, and prefided in the courts of juftice, whofe jurifdiction was not at that time confined merely to the trial of caufes, but extended to affairs of ftate. The ftadtholders fwore allegiance to the princes at their inauguration, jointly with the ftates of the provinces they governed. They likewife took an oath to the ftates, by which they promifed to maintain their fundamental laws and privileges.

It was upon this footing that William the Firft, prince of Orange, was made governor and lieutenant-general of Holland, Zealand, and Utrecht, by Philip the Second, upon his leaving the Low Countries to go into Spain. The troubles beginning foon after, this prince found means to bring about an union, in 1576, between Holland and Zealand; the ftates of which two provinces put into his hands, as far as was in their power, the fovereign authority (for fo long time as they fhould remain in war and under arms), upon the fame footing as Holland had intrufted him with it the year before. In 1581 the fame authority was again renewed to him by Holland, as it was foon after by Zealand likewife; and in 1584, being already elected count of Holland, upon certain conditions he would have been formally invefted with the fovereignty, had not a wretch, hired and employed by the court of Spain, put an end to his life by a horrid affaffination.

In the preamble of the inftruments by which the ftates in 1581 conferred the fovereign authority upon Prince William the Firft, we find thefe remarkable words, which are there fet down as fundamental rules: "That all republics and communities ought to preferve

ferve, maintain, and fortify themfelves by unanimity; which being impoffible to be kept up always among fo many members, often differing in inclinations and fentiments, it is confequently neceffary that the government fhould be placed in the hands of one fingle chief magiftrate." Many good politicians, and the greateft part of the inhabitants of thefe provinces, fince the eftablifhment of the republic, looked upon the ftadtholderian government as an effential part of her conftitution; nor has fhe been without a ftadtholder but twice, that is to fay, from the end of 1650 to 1672, and again from March 1702 till April 1747. The provinces of Friefland and Groningen, with Ommelands, had always a ftadtholder without interruption: their inftructions may be feen in Aitzema; but formerly the powers of the ftadtholder of thefe provinces were confined within narrower bounds, and till William the Fourth there was no ftadtholder of the feven provinces together.

The ftadtholder could not declare war or make peace, but he had, in quality of captain-general of the union, the command in chief of all the forces of the ftate (A); and military perfons were obliged to obey him in every thing that concerned the fervice. He was not limited by inftructions; but he had the important power of giving out orders for the march of troops, and the difpofition of all matters relative to them. He not only directed their marches, but provided for the garrifons, and changed them at pleafure. All military edicts and regulations came from him alone; he conftituted and authorized the high council of war of the United Provinces, and, as captain general of every province, difpofed of all military offices, as far as the rank of colonel inclufively. The higher pofts, fuch as thofe of veltmarfhals, generals, lieutenant-generals, major-generals, were given by the ftates general, who chofe the perfons recommended by his highnefs. He made the governors, commandants, &c. of towns and ftrong places of the republic, and of the barrier. The perfons nominated prefented their inftruments of appointment to their high mightineffes, who provided them with commiffions. The ftates-general had likewife great regard to the recommendation of the prince ftadtholder in the difpofition of thofe civil employments which were in their gift.

The power of the ftadtholder as high-admiral, extended to every thing that concerned the naval force of the republic, and to all the other affairs that were here within the jurifdiction of the admiralty. He prefided at thefe boards either in perfon or by his reprefentatives; and as chief of them all in general, and of every one in particular, he had power to make their orders and inftructions be obferved by themfelves and others. He beftowed the pofts of lieutenant-admiral, vice-admiral, and rear-admiral, who commanded under him; and he made likewife poft-captains.

The ftadtholder granted likewife letters of grace, pardon, and abolition, as well for the crimes called *Communia Delicta*, as for military offences. In Holland and Zealand thefe letters were made out for crimes of the firft fort, in the name of the ftates, with the advice of his highnefs. In military offences he confulted the high council of war; and upon the *communia delicta* he took the advice of the courts of juftice, of the counfellors, committees of the provinces, of the council of ftate, and the tribunals of juftice in the refpective towns, according to the nature of the cafe.

In the provinces of Holland and Zealand, the ftadtholder elected the magiftrates of the towns annually, out of a double number that were returned to him by the towns themfelves.

When any of thefe offices became vacant, which, at the time there was no governor, were in the difpofal of the ftates of Holland, or as formerly in that of the chamber of accounts, the ftadtholder had his choice of two, or, in fome cafes, of three candidates, named by their noble and great mightineffes. He chofe likewife the counfellors, infpectors of the dykes of Rynland, Delfland, and Scheeland, out of three perfons prefented to him by the boards of the counfellors infpectors; which boards were of very ancient eftablifhment in Holland.

His highnefs prefided in the courts of Holland, and in the courts of juftice of the other provinces; and his name was placed at the head of the proclamations and acts, called in Dutch *Mandomenten*, or *Provifion van Juftitie*. In Overyffel and in the province of Utrecht the poffeffors of fiefs held of the prince ftadtholder. He was fupreme curator of the univerfities of Guelder, Friefland, and Groningen; grand forefter and grand veneur in Guelder, in Holland, and other places. In the province of Utrecht, his highnefs, by virtue of the regulation of 1674, difpofed of the provoftfhips and other benefices which remained to the chapters, as alfo of the canonical prebends that fell in the months which were formerly the papal months.

By the firft article of the council of ftate of the United Provinces, the ftadtholder was the firft member of it, and had a right of voting there, with an appointment of 25,000 guilders a-year. He affifted alfo, as often as he thought it for the fervice of the ftate, at the deliberations of the ftates-general, to make propofitions to them, and fometimes alfo at the conferences which the deputies of their high mightineffes held in their different committees, in confequence of their ftanding orders. He likewife affifted at the affemblies of the ftates of each particular province, and at that of the counfellors committees. In Guelder, Holland, and Utrecht, his highnefs had a fhare of the fovereignty, as chief or prefident of the body of nobles; and in Zealand, where he poffeffed the marquifate of Veer and Flufhing, as firft noble, and reprefenting the whole nobility. In his abfence he had

(A) In times of war, however, the ftates had always named deputies for the army, to accompany the ftadtholders in the field, and to ferve them as counfellors in all their enterprifes, particularly in the moft important affairs, fuch as giving battle, or undertaking a fiege, &c. This was always practifed till the acceffion of King William the Third to the crown of Great Britain, and after his death was continued with regard to the general in chief of the army of the republic. In 1747 and 1748 there were likewife deputies with the army, but with more limited power.

had in Zealand his reprefentatives, who had the firft place and the firft voice in all the councils, and the firft of whom was always firft deputy from the province to the affembly of their high mightineffes.

In 1749 the prince ftadtholder was created by the ftates-general, governor-general and fupreme director of the Eaft and Weft India companies; dignities which gave him a great deal of authority and power, and which had never been conferred upon any of his predeceffors, nor had they hitherto been made hereditary. He had his reprefentatives in the feveral chambers of the company, and chofe their directors out of a nomination of three qualified perfons. The prince enjoyed this prerogative in Zealand from the time of his elevation to the ftadtholderate.

The revenues of the ftadtholderate of the feven United Provinces were reckoned (including the 25,000 guilders which the prince enjoyed annually as the firft member of the council of ftate, and what he had from the India company's dividends) to amount to 300,000 guilders a-year. As captain-general of the union, his ferene highnefs had 120,000 guilders per annum; befides 24,000 from Friefland, and 12,000 from Groningen, in quality of captain-general of thofe provinces. In times of war the ftate allowed extraordinary fums to the captain-general for the expence of every campaign.

All thefe powers and privileges were held by the prince of Orange previous to the revolutionary war of France. The influence of the ufurper of that kingdom has extended to the ftates of Holland, and attached them as a province to France under the name of a kingdom, at the head of which is a brother of Bonaparte.

STÆHELINA, a genus of plants belonging to the clafs of fyngenefia, and order of polygamia æqualis; and in the natural fyftem arranged under the 49th order, *Compofitæ*. See BOTANY *Index*.

STAFF, an inftrument ordinarily ufed to reft on in walking. The ftaff is alfo frequently ufed as a kind of natural weapon both of offence and defence; and for feveral other purpofes.

STAFF, a light pole erected in different parts of a fhip, whereon to hoift and difplay the colours.

The principal of thefe is reared immediately over the ftern, to difplay the enfign; another is fixed on the bowfprit, to extend the jack; three more are erected at the three maft heads, or formed by their upper ends, to fhow the flag or pendant of the refpective fquadron or divifion to which the fhip is appropriated. See ENSIGN, MAST, JACK, and PENDANT.

STAFF, in military matters, confifts of a quarter-mafter-general, adjutant-general, and majors of brigade. The ftaff properly exifts only in time of war. See *QUARTER-Mafter General*, &c.

Regimental STAFF, confifts in the adjutant, quarter-mafter, chaplain, furgeon, &c.

STAFF, in mufic, five lines, on which, with the intermediate fpaces, the notes of a fong or piece of mufic are marked.

Fore-STAFF. See *FORE Staff*.

STAFFA, one of the Hebrides or Weftern Iflands of Scotland, remarkable for its bafaltic pillars. It was vifited by Sir Jofeph Banks, who communicated the following account of it to Mr Pennant.

"The little ifland of Staffa lies on the weft coaft of Mull, about three leagues north-eaft from Iona, or Icolumbkill: its greateft length is about an Englifh mile, and its breadth about half a one. On the eaft fide of the ifland is a fmall bay where boats generally land; a little to the fouthward of which the firft appearance of pillarsis to be obferved; they are fmall; and inftead of being placed upright, lie down on their fides, each forming a fegment of a circle. From thence you pafs a fmall cave, above which the pillars, now grown a little larger, are inclining in all directions: in one place in particular, a fmall mafs of them very much refembles the ribs of a fhip. From hence having paffed the cave, which, if it is not low-water, you muft do in a boat, you come to the firft ranges of pillars, which are ftill not above half as large as thofe a little beyond. Over againft this place is a fmall ifland, called in Erfe *Boo-fha-la*, feparated from the main by a channel not many fathoms wide. This whole ifland is compofed of pillars without any ftratum above them; they are ftill fmall, but by much the neateft formed of any about the place.

"The firft divifion of the ifland, for at high water it is divided into two, makes a kind of a cone, the pillars converging together towards the centre: on the other they are in general laid down flat: and in the front next to the main, you fee how beautifully they are packed together, their ends coming out fquare with the bank which they form. All thefe have their tranfverfe fections exact, and their furfaces fmooth; which is by no means the cafe with the large ones, which are cracked in all directions. I muft queftion, however, if any part of this whole ifland of Boo-fha-la is two feet in diameter.

"The main ifland oppofite to Boo-fha-la, and farther towards the north-weft, is fupported by ranges of pillars pretty erect, and, though not tall (as they are not uncovered to the bafe), of large diameters; and at their feet is an irregular pavement, made by the upper fides of fuch as have been broken off, which extends as far under water as the eye can reach. Here the forms of the pillars are apparent; thefe are of three, four, five, fix, and feven fides; but the numbers of five and fix are by much the moft prevalent. The largeft I meafured was of feven; it was four feet five inches in diameter.

"The furfaces of thefe large pillars, in general, are rough and uneven, full of cracks in all directions; the tranfverfe figures in the upright ones never fail to run in their true directions. The furfaces upon which we walked were often flat, having neither concavity nor convexity; the larger number, however, was concave, though fome were very evidently convex. In fome places, the interftices within the perpendicular figures were filled up with a yellow fpar: in one place, a vein paffed in among the mafs of pillars, carrying here and there fmall threads of fpar. Though they were broken and cracked through in all directions, yet their perpendicular figures might eafily be traced: from whence it is eafy to infer, that whatever the accident might have been that caufed the diflocation, it happened after the formation of the pillars.

"From hence proceeding along fhore, you arrive at Fingal's cave. Its dimenfions I have given in the form of a table:

	Feet.	In.
Length of the cave from the rock without,	371	6
From the pitch of the arch,	250	0

Breadth of ditto at the mouth,	53	7
At the farther end,	20	0
Height of the arch at the mouth,	117	6
At the end,	70	0
Height of an outside pillar,	39	6
Of one at the north-west corner,	54	0
Depth of water at the mouth,	18	0
At the bottom,	9	0

"The cave runs into the rock in the direction of north-east by east by the compass.

"Proceeding farther to the north-west, you meet with the highest ranges of pillars; the magnificent appearance of which is past all description. Here they are bare to their very basis, and the stratum below them is also visible: in a short time, it rises many feet above the water, and gives an opportunity of examining its quality. Its surface is rough, and has often large lumps of stone sticking in it as if half immersed: itself, when broken, is composed of a thousand heterogeneous parts, which together have very much the appearance of a lava; and the more so, as many of the lumps appear to be of the very same stone of which the pillars are formed. This whole stratum lies in an inclined position, dipping gradually towards the south-east. As hereabouts is the situation of the highest pillars, I shall mention my measurements of them, and the different strata in this place, premising, that the measurements were made with a line, held in the hand of a person who stood at the top of the cliff, and reaching to the bottom; to the lower end of which was tied a white mark, which was observed by one who staid below for the purpose: when this mark was set off from the water, the person below noted it down, and made signal to him above, who made then a mark in his rope: whenever this mark passed a notable place, the same signal was made, and the name of the place noted down as before: the line being all hauled up, and the distances between the marks measured and noted down, gave, when compared with the book kept below, the distances, as for instance in the cave:

"N° 1. in the book below, was called from the water to the foot of the first pillar in the book above; N° 1. gave 36 feet eight inches, the highest of that ascent, which was composed of broken pillars.

"N° 1. Pillar at the west corner of Fingal's cave.

	Feet.	In.
1 From the water to the foot of the pillar,	12	10
2 Height of the pillar,	37	3
3 Stratum above the pillar,	66	9

"N° 2. Fingal's cave.

1 From the water to the foot of the pillar,	36	8
2 Height of the pillar	39	6
3 From the top of the pillar to the top of the arch,	31	4
4 Thickness of the stratum above,	34	4
By adding together the three first measurements, we got the height of the arch from the water,	117	6

"N° 3. Corner pillar to the westward of Fingal's cave.

Stratum below the pillar of lava-like matter,	11	0
Length of pillar,	54	0
Stratum above the pillar,	61	6

"N° 4. Another part to the westward.

Stratum below the pillar,	17	1
Height of the pillar,	50	0
Stratum above.	51	1

"N° 5. Another pillar farther to the westward.

Stratum below the pillar,	19	8
Height of the pillar,	55	1
Stratum above,	54	7

"The stratum above the pillars, which is here mentioned, is uniformly the same, consisting of numberless small pillars, bending and inclining in all directions, sometimes so irregularly that the stones can only be said to have an inclination to assume a columnar form; in others more regular, but never breaking into or disturbing the stratum of large pillars, whose tops everywhere keep an uniform and regular line.

"Proceeding now along the shore round the north end of the island, you arrive at *Oua na scarve*, or the Corvorant's Cave. Here the stratum under the pillars is lifted up very high; the pillars above it are considerably less than those at the north-west end of the island, but still very considerable. Beyond is a bay, which cuts deep into the island, rendering it in that place not more than a quarter of a mile over. On the sides of this bay, especially beyond a little valley, which almost cuts the island into two, are two stages of pillars, but small; however, having a stratum between them exactly the same as that above them, formed of innumerable little pillars, shaken out of their places, and leaning in all directions.

"Having passed this bay, the pillars totally cease; the rock is of a dark brown stone, and no signs of regularity occur till you have passed round the south-east end of the island (a space almost as large as that occupied by the pillars), which you meet again on the west side, beginning to form themselves irregularly, as if the stratum had an inclination to that form, and soon arrive at the bending pillars where I began.

"The stone of which the pillars are formed, is a coarse kind of basaltes, very much resembling the Giant's Causeway in Ireland, though none of them are near so neat as the specimens of the latter which I have seen at the British Museum; owing chiefly to the colour, which in ours is a dirty brown, in the Irish a fine black; indeed the whole production seems very much to resemble the Giant's Causeway."

STAFFORD, the county town of Staffordshire, in W. Long. 2. 0. N. Lat. 53. 0. It stands on the river Sow, has two parish-churches, a fine square market-place, and a flourishing cloth-manufacture. It sends two members to parliament, and is 135 miles from London.

STAFFORDSHIRE, a county of England, bounded on the south by Worcestershire, by Cheshire and Derbyshire on the north, by Warwickshire and Derbyshire on the east, and Shropshire and Cheshire on the west. The length is reckoned 62 miles, the breadth 33, and the circumference 180. It contains five hundreds, 150 parishes, 810,000 acres, 18 market-towns, and 239,153

239,153 inhabitants. The air, except in thofe parts that are called the Moorlands and Woodlands, and about the mines, is good, efpecially upon the hills, where it is accounted very fine. The foil in the northern mountainous parts is not fertile; but in the middle, where it is watered by the Trent, the third river in England, it is both fruitful and pleafant, being a mixture of arable and meadow grounds. In the fouth, it abounds not only with corn, but with mines of iron and pits of coal. The principal rivers of this county, befides the Trent, which runs almoft through the middle of it, and abounds with falmon, are the Dove and Tame, both of which are well ftored with fifh. In this county are alfo a great many lakes, and meres or pools, as they are called; which, having ftreams either running into them or from them, cannot be fuppofed to be of any great prejudice to the air; they yield plenty of fifh. In divers parts of the county are medicinal waters, impregnated with different forts of minerals, and confequently of different qualities and virtues; as thofe at Hints and Brefsford-houfe, which are mixed with bitumen; thofe at Ingeftre, Codfalwood, and Willoughbridge park, which are fulphureous. Of the faline kind are the Brine-pits at Chertley, Epfom, Penfnet-clofe, of which very good falt is made. There is a well at Newcaftle-under-Line that is faid to cure the king's evil; another called *Elder-well* near Blemhill, faid to be good for fore eyes; and a third called the *Spa*, near Wolverhampton.

Great flocks of fheep are bred in this county, efpecially in the moorlands, or mountains of the northern part of it; but the wool is faid to be fomewhat coarfer than that of many other counties. Of this wool, however, they make a variety of manufactures, particularly felts. In the low grounds along the rivers are rich paftures for black cattle; and vaft quantities of butter and cheefe are made. In the middle and fouthern parts not only grain of all kinds, but a great deal of hemp and flax are raifed. This country produces alfo lead, copper, iron; marble, alabafter, millftones, limeftone; coal, falt, and marles of feveral forts and colours; brick-earth, fullers earth, and potters clay, particularly a fort ufed in the glafs manufacture at Amblecot, and fold at feven-pence a bufhel; tobacco-pipe clay; a fort of reddifh earth called *flip*, ufed in painting divers veffels; red and yellow ochres; fire-ftones for hearths of iron furnaces, ovens, &c.; iron-ftones of feveral forts; blood-ftones, or hæmatites, found in the brook Tent, which, when wet a little, will draw red lines like ruddle; quarry-ftones, and grind-ftones. For fuel the country is well fupplied with turf, peat, and coal of feveral forts, as cannel-coal, peacock-coal, and pit-coal. The peacock-coal is fo called, becaufe, when turned to the light, it difplays all the colours of the peacock's tail; but it is fitter for the forge than the kitchen. Of the pit-coal there is an inexhauftible ftore: it burns into white afhes, and leaves no fuch cinder as that of the Newcaftle coal. It is not ufed for malting till it is charred, and in that ftate it makes admirable winter-fuel for a chamber.

This county is in the diocefe of Litchfield and Coventry, and the Oxford circuit. It fends ten members to parliament; namely, two for the county, two for the city of Litchfield, two for Stafford, two for Newcaftle-under-Line, and two for Tamworth.

Stag-Beetle. See Lucanus, Entomology *Index*.

STAGE, in the modern drama, the place of action and reprefentation, included between the pit and the fcenes, and anfwering to the profcenium or pulpitum of the ancients. See Playhouse and Theatre.

STAGGERS. See Farriery *Index*.

STAHL, George Ernest, an eminent German chemift, was born in Franconia in 1660, and chofen profeffor of medicine at Hall, when a univerfity was founded in that city in 1694. The excellency of his lectures while he filled that chair, the importance of his various publications, and his extenfive practice, foon raifed his reputation to a very great height. He received an invitation to Berlin in 1716, which having accepted, he was made counfellor of ftate and phyfician to the king. He died in 1734, in the 75th year of his age. Stahl is without doubt one of the greateft men of which the annals of medicine can boaft: his name marks the commencement of a new and more illuftrious era in chemiftry. He was the author of the doctrine of phlogifton, which, though now completely overturned by the difcoveries of Lavoifier and others, was not without its ufe; as it ferved to combine the fcattered fragments of former chemifts into a fyftem, and as it gave rife to more accurate experiments and a more fcientific view of the fubject, to which many of the fubfequent difcoveries were owing. This theory maintained its ground for more than half a century, and was received and fupported by fome of the moft eminent men which Europe has produced; a fufficient proof of the ingenuity and the abilities of its author. He was the author alfo of A Theory of Medicine, founded upon the notions which he entertained of the abfolute dominion of mind over body; in confequence of which, he affirmed, that every mufcular action is a voluntary act of the mind, whether attended with confcioufnefs or not. This theory he and his followers carried a great deal too far, but the advices at leaft which he gives to attend to the ftate of the mind of the patient are worthy of the attention of phyficians.

His principal works are, 1. *Experimenta et Obfervationes Chemicæ et Phyficæ*, Berlin, 1731, 8vo. 2. *Differtationes Medicæ*, Hall, 2 vols 4to. This is a collection of thefes. 3. *Theoria Medica vera*, 1737, 4to. 4. *Opufculum Chymico-phyfico-medicum*, 1740, 4to. 5. A Treatife on Sulphur, both Inflammable and Fixed, written in German. 6. *Negotium Otiofum*, Hall, 1720, 4to. It is in this treatife chiefly that he eftablifhes his fyftem concerning the action of the foul upon the body. 7. *Fundamenta Chymicæ Dogmaticæ et Experimentalis*, Nuremberg, 1747, 3 vols 4to. 8. A treatife on Salts, written in German. 9. *Commentarium in Metallurgiam Beccheri*, 1723.

STAINING *or* Colouring *of* Bone, Horn, Marble, Paper, Wood, &c. See thefe articles.

STAIRCASE, in *Architecture*, an afcent inclofed between walls, or a baluftrade confifting of ftairs or fteps, with landing places and rails, ferving to make a communication between the feveral ftories of a houfe. See Architecture, N° 89, &c.

STALACTITES, in *Mineralogy*, cryftalline fpars formed into oblong, conical, round, or irregular bodies, compofed of various crufts, and ufually found hanging in form of ificles from the roofs of grottoes, &c.

STALAGMITIS, a genus of the monœcia order, belonging

belonging to the polygamia clafs of plants; and in the natural method ranking under the 38th order, *Tricoccæ*. See BOTANY and MATERIA MEDICA *Index*.

STALE, among fportfmen, a living fowl put in a place to allure and bring others where they may be taken. For want of thefe, a bird fhot, his entrails taken out, and dried in an oven in his feathers, with a ftick thruft through to keep it in a convenient pofture, may ferve as well as a live one.

STALE is alfo a name for the urine of cattle.

ANIMATED STALK. This remarkable animal was found by Mr Ives at Cuddalore: and he mentions feveral kinds of it; fome appearing like dry ftraws tied together, others like grafs; fome have bodies much larger than others, with the addition of two fcaly imperfect wings; their neck is no bigger than a pin, but twice as long as their bodies; their heads are like thofe of an hare, and their eyes vertical and very brifk. They live upon flies, and catch thefe infects very dexteroufly with the two fore-feet, which they keep doubled up in three parts clofe to their head, and dart out very quick on the approach of their prey; and when they have caught it, they eat it very voracioufly, holding it in the fame manner as a fquirrel does its food. On the outer joints of the fore-feet are feveral very fharp hooks for the eafier catching and holding of their prey; while, with the other feet, which are four in number, they take hold of trees or any other thing, the better to furprife whatever they lie in wait for. They drink like a horfe, putting their mouths into the water. Their excrements, which are very white, are almoft as large as the body of the animal, and as the natives fay, dangerous to the eyes.

STALLION, or STONE-HORSE, in the manege, a horfe defigned for the covering of mares, in order to propagate the fpecies. See EQUUS, MAMMALIA *Index*.

STAMFORD, an ancient town of Lincolnfhire in England; feated on the river Welland, on the edge of Northamptonfhire. It is a large handfome place, containing fix parifh-churches, feveral good ftreets, and fine buildings. It had formerly a college, the ftudents of which removed to Brazen Nofe college in Oxford. It has no confiderable manufactories, but deals chiefly in malt. W. Long. 0. 31. N. Lat. 54. 42.

STAMINA, in *Botany*, are thofe upright filaments which, on opening a flower, we find within the corolla furrounding the piftillum. According to Linnæus, they are the male organs of generation, whofe office it is to prepare the pollen. Each ftamen confifts of two diftinct parts, viz. the FILAMENTUM and the ANTHERA.

STAMINA, in the animal body, are defined to be thofe fimple original parts which exifted firft in the embryo or even in the feed; and by whofe diftinction, augmentation, and accretion by additional juices, the animal body at its utmoft bulk is fuppofed to be formed.

STAMP-DUTIES, a branch of the perpetual revenue. See REVENUE.

In Great Britain there is a tax impofed upon all parchment and paper, whereon any legal proceedings or private inftruments of almoft any nature whatfoever are written; and alfo upon licenfes for retailing wines, of all denominations; upon all almanacs, newfpapers, advertifements, cards, dice, &c. Thefe impofts are very various; being higher or lower, not fo much according to the value of the property transferred, as according to the nature of the deed. The higheft do not exceed fix pounds upon every fheet of paper or fkin of parchment; and thefe high duties fall chiefly upon grants from the crown, and upon certain law proceedings, without any regard to the value of the fubject. There are in Great Britain no duties on the regiftration of deeds or writings, except the fees of the officers who keep the regifter; and thefe are feldom more than a reafonable recompenfe for their labour. The crown derives no revenue from them.

Smith's Wealth of Nations, vol. iii.

The ftamp-duties conftitute a tax which, though in fome inftances it may be heavily felt, by greatly increafing the expence of all mercantile as well as legal proceedings, yet (if moderately impofed) is of fervice to the public in general, by authenticating inftruments, and rendering it much more difficult than formerly to forge deeds of any ftanding; fince, as the officers of this branch of the revenue vary their ftamps frequently, by marks perceptible to none but themfelves, a man that would forge a deed of King William's time, muft know and be able to counterfeit the ftamp of that date alfo. In France and fome other countries the duty is laid on the contract itfelf, not on the inftrument in which it is contained; as, with us too in England (befides the ftamps on the indentures), a tax is laid, by ftatute 8 Ann. c. 9. on every apprentice-fee; of 6d. in the pound if it be 50l. or under, and 1s, in the pound if a greater fum: but this tends to draw the fubject into a thoufand nice difquifitions and difputes concerning the nature of his contract, and whether taxable or not; in which the farmers of the revenue are fure to have the advantage. Our general method anfwers the purpofes of the ftate as well, and confults the eafe of the fubject much better. The firft inftitution of the ftamp-duties was by ftatute 5 and 6 W. and M. c 21. and they have fince, in many inftances, been increafed to five times their original amount.

STANCHION, or STANCHIONS, a fort of fmall pillars of wood or iron ufed for various purpofes in a fhip; as to fupport the decks, the quarter-rails, the nettings, the awnings, &c. The firft of thofe are two ranges of fmall columns fixed under the beams, throughout the fhip's length between decks; one range being on the ftarboard and the other on the larboard fide of the hatchways. They are chiefly intended to fupport the weight of the artillery.

STAND, in commerce, a weight from two hundred and an half to three hundred of pitch.

STANDARD, in *War*, a fort of banner or flag borne as a fignal for the joining together of the feveral troops belonging to the fame body.

STANDARD, in *Commerce*, the original of a weight, meafure, or coin, committed to the keeping of a magiftrate, or depofited in fome public place, to regulate, adjuft, and try the weights ufed by particular perfons in traffic. See MONEY.

STANHOPE PHILIP DORMER, EARL OF CHESTERFIELD, was born in 1695, and educated in Trinity-hall, Cambridge; which place he left in 1714, when, by his own account, he was an abfolute pedant. In this character he went abroad, where a familiarity with good company foon convinced him he was totally miftaken in almoft all his notions: and an attentive ftudy of the air, manner, and addrefs of people of fafhion, foon polifhed a man whofe predominant defire was to pleafe; and who, as it afterwards appeared, valued exterior accomplifh-

Stanhope. ments beyond any other human acquirement. While Lord Stanhope, he got an early feat in parliament; and in 1722, fucceeded to his father's eftate and titles. In 1728, and in 1745, he was appointed ambaffador extraordinary and plenipotentiary to Holland: which high character he fupported with the greateft dignity; ferving his own country, and gaining the efteem of the ftates-general. Upon his return from Holland, he was fent lord-lieutenant of Ireland; and during his adminiftration there, gave general fatisfaction to all parties. He left Dublin in 1746, and in October fucceeded the earl of Harrington as fecretary of ftate, in which poft he officiated until February 6th 1748. Being feized with a deafnefs in 1752 that incapacitated him for the pleafures of fociety, he from that time led a private and retired life, amufing himfelf with books and his pen; in particular, he engaged largely as a volunteer in a periodical mifcellaneous paper called *The World*, in which his contributions have a diftinguifhed degree of excellence. He died in 1773, leaving a character for wit and abilities that had few equals. He diftinguifhed himfelf by his eloquence in parliament on many important occafions; of which we have a characteriftic inftance, of his own relating. He was an active promoter of the bill for altering the ftyle; on which occafion, as he himfelf writes in one of his letters to his fon, he made fo eloquent a fpeech in the houfe, that every one was pleafed, and faid he had made the whole very clear to them; "when (fays he), God knows, I had not even attempted it. I could juft as foon have talked Celtic or Sclavonian to them, as aftronomy; and they would have underftood me full as well." Lord Macclesfield, one of the greateft mathematicians in Europe, and who had a principal hand in framing the bill, fpoke afterwards, with all the clearnefs that a thorough knowledge of the fubject could dictate; but not having a flow of words equal to Lord Chefterfield, the latter gained the applaufe from the former, to the equal credit of the fpeaker and the auditors. The high character Lord Chefterfield fupported during life, received no fmall injury foon after his death, from a fuller difplay of it by his own hand. He left no iffue by his lady, but had a natural fon, Philip Stanhope, Efq. whofe education was for many years a clofe object of his attention, and who was afterward envoy extraordinary at the court of Drefden, but died before him. When Lord Chefterfield died, Mr Stanhope's widow publifhed a courfe of letters, written by the father to the fon, filled with inftructions fuitable to the different gradations of the young man's life to whom they were addreffed. Thefe letters contain many fine obfervations on mankind, and rules of conduct: but it is obfervable that he lays a greater ftrefs on exterior accomplifhments and addrefs, than on intellectual qualifications and fincerity; and allows greater latitude to fafhionable pleafures than good morals will juftify, efpecially in paternal inftructions. Hence it is that a celebrated writer §, and of manners fomewhat different from thofe of the polite earl of Chefterfield, is faid to have obferved of thefe letters, that "they inculcate only the morals of a whore, with the manners of a dancing-mafter."

§ *Dr Johnfon.*

Stanhope, *Dr George*, an eminent divine, was born at Hertifhorn in Derbyfhire, in the year 1660. His father was rector of that place, vicar of St Margaret's church in Leicefter, and chaplain to the earls of Chefterfield and Clare. His grandfather, Dr George Stanhope, was chaplain to James I. and Charles I.; had the chancellorfhip of York, where he was alfo a canon-refidentiary, held a prebend, and was rector of Weldrake in that county. He was for his loyalty driven from his home with eleven children; and died in 1644. Our author was fent to fchool, firft at Uppingham in Rutland, then at Leicefter; afterwards removed to Eaton; and thence chofen to King's college in Cambridge, in the place of W. Cleaver. He took the degree of B. A. in 1681; M. A. 1685; was elected one of the fyndics for the univerfity of Cambridge, in the bufinefs of Alban Francis, 1687; minifter of Quoi near Cambridge, and vice-proctor, 1688; was that year preferred to the rectory of Tring in Hertfordfhire, which after fome time he quitted. He was in 1689 prefented to the vicarage of Lewifham in Kent by Lord Dartmouth, to whom he had been chaplain, and tutor to his fon. He was alfo appointed chaplain to King William and Queen Mary, and continued to enjoy that honour under Queen Anne. He commenced D. D. July 5th 1697, performing all the offices required to that degree publicly and with great applaufe. He was made vicar of Deptford in 1703; fucceeded Dr Hooper as dean of Canterbury the fame year; and was thrice chofen prolocutor of the lower houfe of convocation. His uncommon diligence and induftry, affifted by his excellent parts, enriched him with a large ftock of polite, folid, and ufeful learning. His difcourfes from the pulpit were equally pleafing and profitable; a beautiful intermixture of the cleareft reafoning with the pureft diction, attended with all the graces of a juft elocution. The good Chriftian, the folid divine, and the fine gentleman, in him were happily united. His converfation was polite and delicate, grave without precifenefs, facetious without levity. His piety was real and rational, his charity great and univerfal, fruitful in acts of mercy, and in all good works. He died March 18th 1728, aged 68 years; and was buried in the chancel of the church at Lewifham. The dean was twice married: firft to Olivia Cotton, by whom he had one fon and four daughters. His fecond lady, who was fifter to Sir Charles Wager, furvived him, dying October 1ft 1730, aged about 54. One of the dean's daughters was married to a fon of Bifhop Burnet. Bifhop Moore of Ely died the day before Queen Anne; who, it has been faid, defigned our dean for that fee when it fhould become vacant. Dr Felton fays, "The late dean of Canterbury is excellent in the whole. His thoughts and reafoning are bright and folid. His ftyle is juft, both for the purity of the language and for the ftrength and beauty of expreffion; but the periods are formed in fo peculiar an order of the words, that it was an obfervation, nobody could pronounce them with the fame grace and advantage as himfelf." His writings, which are an ineftimable treafure of piety and devotion are, A Paraphrafe and Comment upon the Epiftles and Gofpels, 4 vols, 1705, 8vo. Sermons at Boyle's Lectures, 1706, 4to. Fifteen Sermons, 1700, 8vo. Twelve Sermons on feveral Occafions, 1727, 8vo. Thomas à Kempis, 1696, 8vo. Epictetus's Morals, with Simplicius's Comment, and the Life of Epictetus, 1700, 8vo. Parfon's Chriftian Directory, 1716, 8vo. Rochefoucault's Maxims, 1706, 8vo. A Funeral Sermon on Mr Richard Sare bookfeller, 1724; two editions 4to. Twenty Sermons, publifhed fingly between

between the years 1692 and 1724. Private Prayers for every Day in the Week, and for the feveral Parts of each Day; tranflated from the Greek Devotions of Bifhop Andrews, with Additions, 1730. In his tranflations, it is well known, Dr Stanhope did not confine himfelf to a ftrict and literal verfion: he took the liberty of paraphrafing, explaining, and improving upon his author; as will evidently appear (not to mention any other work) by the flighteft perufal of St Auguftine's Meditations, and the Devotions of Bifhop Andrews.

STANISLAUS Leczinski, king of Poland, was born at Leopold the 20th of October 1677. His father was a Polifh nobleman, diftinguifhed by his rank and the important offices which he held, but ftill more by his firmnefs and courage. Staniflaus was fent ambaffador in 1704 by the affembly of Warfaw to Charles XII. of Sweden, who had conquered Poland. He was at that time 27 years old, was general of Great Poland, and had been ambaffador extraordinary to the Grand Signior in 1699. Charles was fo delighted with the franknefs and fincerity of his deportment, and with the firmnefs and fweetnefs which appeared in his countenance, that he offered him the crown of Poland, and ordered him to be crowned at Warfaw in 1705. He accompanied Charles XII. into Saxony, where a treaty was concluded with King Auguftus in 1705, by which that prince refigned the crown, and acknowledged Staniflaus king of Poland. The new monarch remained in Saxony with Charles till 1707, when they returned into Poland and attacked the Ruffians, who were obliged to evacuate that kingdom in 1708. But Charles being defeated by Peter the Great in 1709, Auguftus returned into Poland, and being affifted by a Ruffian army, obliged Staniflaus to retire firft into Sweden, and afterwards into Turkey. Soon after he took up his refidence at Weiffenburg, a town in Alface. Auguftus difpatched Sum his envoy to France to complain of this; but the duke of Orleans, who was then regent, returned this anfwer: "Tell your king, that France has always been the afylum of unhappy princes." Staniflaus lived in obfcurity till 1725, when Louis XV. efpoufed the princefs Mary his daughter. Upon the death of King Auguftus in 1733, he returned to Poland in hopes of remounting the throne of that kingdom. A large party declared for him; but his competitor the young elector of Saxony, being fupported by the emperor Charles VI. and the emprefs of Ruffia, was chofen king, though the majority was againft him. Dantzic, to which Staniflaus had retired, was quickly taken, and the unfortunate prince made his efcape in difguife with great difficulty, after hearing that a price was fet upon his head by the Ruffians. When peace was concluded in 1736 between the emperor and France, it was agreed that Staniflaus fhould abdicate the throne, but that he fhould be acknowledged king of Poland and grand duke of Lithuania, and continue to bear thefe titles during life; that all his effects and thofe of the queen his fpoufe fhould be reftored; that an amnefty fhould be declared in Poland for all that was paft, and that every perfon fhould be reftored to his poffeffions, rights, and privileges: that the elector of Saxony fhould be acknowledged king of Poland by all the powers who acceded to the treaty: that Staniflaus fhould be put in peaceable poffeffion of the duchies of Lorraine and Bar; but that immediately after his death thefe duchies fhould be united for ever to the crown of France. Staniflaus fucceeded a race of princes in Lorraine, who were beloved and regretted: and his fubjects found their ancient fovereigns revived in him. He tafted then the pleafure which he had fo long defired, the pleafure of making men happy. He affifted his new fubjects; he embellifhed Nancy and Luneville; he made ufeful eftablifhments; he founded colleges and built hofpitals. He was engaged in thefe noble employments, when an accident occafioned his death. His night-gown caught fire, and burnt him fo feverely before it could be extinguifhed, that he was feized with a fever, and died the 23d of February 1766. His death occafioned a public mourning: the tears of his fubjects indeed are the beft eulogium upon this prince. In his youth he had accuftomed himfelf to fatigue, and had thereby ftrengthened his mind as well as his conftitution. He lay always upon a kind of mattrefs, and feldom required any fervice from his domeftics. He was temperate, liberal, adored by his vaffals, and perhaps the only nobleman in Poland who had any friends. He was in Lorraine what he had been in his own country, gentle, affable, compaffionate, treating his fubjects like equals, participating their forrows and alleviating their misfortunes. He refembled completely the picture of a philofopher which he himfelf has drawn. "The true philofopher (faid he) ought to be free from prejudices, and to know the value of reafon: he ought neither to think the higher ranks of life of more value than they are, nor to treat the lower orders of mankind with greater contempt than they deferve: he ought to enjoy pleafures without being a flave to them, riches without being attached to them, honours without pride or vanity: he ought to fupport difgraces without either fearing or courting them: he ought to reckon what he poffeffes fufficient for him, and to regard what he has not as ufelefs: he ought to be eqoal in every fortune, always tranquil, always gay: he ought to love order, and to obferve it in all his actions: he ought to be fevere to himfelf, but indulgent to others: he ought to be frank and ingenuous without rudenefs, polite without falfehood, complaifant without bafenefs: he ought to have the courage to difregard every kind of glory, and to reckon as nothing even philofophy itfelf." Such was Staniflaus in every fituation. His temper was affectionate. He told his treafurer one day to put a certain officer on his lift, to whom he was very much attached: "In what quality (faid the treafurer) fhall I mark him down?" "As my friend" (replied the monarch). A young painter conceiving hopes of making his fortune if his talents were made known to Staniflaus, prefented him with a picture, which the courtiers criticifed feverely. The prince praifed the performance, and paid the painter very generoufly: then turning to his courtiers, he faid, "Do ye not fee, gentlemen, that this poor man muft provide for his family by his abilities? if you difcourage him by your cenfures, he is undone. We ought always to affift men; we never gain any thing by hurting them." His revenues were fmall; but were we to judge of him by what he did, we fhould probably reckon him the richeft potentate in Europe. A fingle inftance will be fufficient to fhow the well-judged economy with which his benevolent plans were conducted. He gave 18,000 crowns to the magiftrates of Bar to be employed in purchafing grain, when at a low price, to be fold out again to the poor at a moderate rate when the

the price should rise above a certain sum. By this arrangement (say the authors of *Dictionaire Historique*), the money increases continually, and its good effects may in a short time be extended over the whole province.

He was a protector of the arts and sciences: he wrote several works of philosophy, politics, and morality, which were collected and published in France in 1765, in 4 vols, 8vo, under the title of *Oeuvres de Philosophe Bienfaisant*, "the works of the Benevolent Philosopher."

STANITZAS, villages or small districts of the banks of the Don, inhabited by Cossacs.

STANLEY, Thomas, a learned English writer in the 17th century, was the son of Sir Thomas Stanley of Cumberlow-Green in Herefordshire, knight. He was born at Cumberlow about 1644, and educated in his father's house, whence he removed to the university of Cambridge. He afterwards travelled; and, upon his return to England, prosecuted his studies in the Middle Temple. He married, when young, Dorothy, the eldest daughter of Sir James Engan of Flower, in Northamptonshire. He wrote, 1. A volume of Poems. 2. History of Philosophy, and Lives of the Philosophers. 3. A Translation of Eschylus, with a Commentary; and several other works. He died in 1678.

STANNARIES, the mines and works where tin is dug and purified; as in Cornwall, Devonshire, &c.

STANNARY courts, in Devonshire and Cornwall, for the administration of justice among the tinners therein. They are held before the lord-warden and his substitutes, in virtue of a privilege granted to the workers in the tin-mines there, to sue and be sued only in their own courts, that they may not be drawn from their business, which is highly profitable to the public, by attending their law-suits in other courts. The privileges of the tinners are confirmed by a charter, 33 Edw. I. and fully expounded by a private statute, 50 Edw. III. which has since been explained by a public act. 16 Car. I. c. 15. What relates to our present purpose is only this: That all tinners and labourers in and about the stannaries shall, during the time of their working therein, *bona fide*, be privileged from suits of other courts, and be only pleaded in the stannary court in all matters, excepting pleas of land, life, and member. No writ of error lies from hence to any court in Westminster-hall; as was agreed by all the judges, in 4 Jac. I. But an appeal lies from the steward of the court to the underwarden; and from him to the lord-warden; and thence to the privy-council of the prince of Wales, as duke of Cornwall, when he hath had livery or investiture of the same. And from thence the appeal lies to the king himself, in the last resort.

Blackstone's Comment. vol. iii. p. 79 and 80.

STANNUM, Tin. See Tin, Chemistry and Mineralogy *Index*.

STANZA, in *Poetry*, a number of lines regularly adjusted to each other; so much of a poem as contains every variation of measure or relation of rhyme used in that poem.

STAPELIA, a genus of plants belonging to the class pentandria and order digynia, and in the natural orders arranged under the *Succulentæ*. See Botany *Index*.—This singular tribe of plants is peculiar to the sandy deserts of Africa and Arabia. They are extremely succulent. From this peculiarity of structure, the power of retaining water to support and nourish them, they are enabled to live during the prevalent droughts of those arid regions. On this account the stapelia has been compared to the camel; and we are told that, by a very apt similitude, it has been denominated "the *camel* of the vegetable kingdom." We must confess ourselves quite at a loss to see the propriety or aptitude of this comparison. In many parts of the animal and vegetable economy there is doubtless a very obvious and striking analogy: but this analogy has been often carried too far; much farther than fair experiment and accurate observation will in any degree support. It is perhaps owing to this inaccuracy in observing the peculiarity of structure and diversity of functions, that a resemblance is supposed to exist, as in the present case, where in reality there is none. The camel is provided with a bag or fifth stomach, in addition to the four with which ruminant animals are furnished. This fifth stomach is destined as a reservoir to contain water; and it is sufficiently capacious to receive a quantity of that necessary fluid, equal to the wants of the animal, for many days: and this water, as long as it remains in the fifth stomach, is said to be perfectly pure and unchanged. The *stapelia*, and other succulent plants, have no such reservoir. The water is equally, or nearly so, diffused through the whole plant. Every vessel and every cell is fully distended. But besides, this water, whether it be received by the roots, or absorbed from the atmosphere, has probably undergone a complete change, and become, after it has been a short time within the plant, a fluid possessed of very different qualities.

The peculiar economy in the stapelia, and other succulent plants, seems to exist in the absorbent and exhalant systems. The power of absorption is as much increased as the power of the exhalant or perspiratory vessels is diminished. In these plants, a small quantity of nourishment is required. There is no solid part to be formed, no large fruit to be produced. They generally have very small leaves, often are entirely naked; so that taking the whole plant, a small surface only is exposed to the action of light and heat, and consequently a much smaller proportion of water is decomposed than in plants which are much branched and furnished with leaves.

Two species of stapelia only were known at the beginning of the century. The unfortunate Forskal, the companion of Niebhur, who was sent out by the king of Denmark to explore the interior of Arabia, and who fell a sacrifice to the pestilential diseases of those inhospitable regions, discovered two new species. Thunberg, in his *Prodromus*, has mentioned five more. Forty new species have been discovered by Mr Masson of Kew Gardens, who was sent out by his present Majesty for the purpose of collecting plants round the Cape of Good Hope. Descriptions of these, with elegant and highly finished coloured engravings, have lately been published. They are chiefly natives of the extensive deserts called *Karro*, on the western side of the Cape.

STAPHYLEA, Bladder-nut, a genus of plants belonging to the class of pentandria and order of trigynia; and in the natural system arranged under the 23d order, *Trihilatæ*. See Botany *Index*.

STAPHYLINUS, a genus of insects belonging to the order of coleoptera. See Entomology *Index*.

STAPLE, primarily signifies a public place or market, whither merchants, &c. are obliged to bring their goods to be bought by the people; as the Greve, or the places along the Seine, for sale of wines and corn, at Paris, whither the merchants of other parts are obliged to bring those commodities.

Formerly, the merchants of England were obliged to carry their wool, cloth, lead, and other like staple commodities of this realm, in order to expose them by wholesale; and these staples were appointed to be constantly kept at York, Lincoln, Newcastle-upon-Tyne, Norwich, Westminster, Canterbury, Chichester, Winchester, Exeter, and Bristol; in each whereof a public mart was appointed to be kept, and each of them had a court of the mayor of the staple, for deciding differences, held according to the law-merchant, in a summary way.

STAR, in *Astronomy*, a general name for all the heavenly bodies, which, like so many brilliant studs, are dispersed throughout the whole heavens. The stars are distinguished, from the phenomena of their motion, &c. into fixed, and erratic or wandering stars: these last are again distinguished into the greater luminaries, viz. the sun and moon; the planets, or wandering stars, properly so called, and the comets; which have been all fully considered and explained under the article ASTRONOMY. As to the fixed stars, they are so called, because they seem to be fixed, or perfectly at rest, and consequently appear always at the same distance from each other.

Falling STARS, in *Meteorology*, fiery meteors which dart through the sky in form of a star. See METEOR.

Twinkling of the STARS. See OPTICS.

STAR, is also a badge of honour, worn by the knights of the garter, bath, and thistle. See GARTER.

STAR of Bethlehem. See ORNITHOGALUM, BOTANY *Index*

STAR, in *Fortification*, denotes a small fort, having five or more points, or saliant and re-entering angles, flanking one another, and their faces 90 or 100 feet long.

Court of STAR-CHAMBER, (camera stellata), a famous, or rather infamous, English tribunal, said to have been so called either from a Saxon word signifying to *steer* or govern; or from its punishing the *crimen stellionatus*, or cosenage; or because the room wherein it sat, the old council-chamber of the palace of Westminster, (Lamb. 148.) which is now converted into the lottery-office, and forms the eastern side of New-Palace yard, was full of windows; or, (to which Sir Edward Coke, 4 Inst. 66. accedes), because *haply* the roof thereof was at the first garnished with gilded *stars*. As all these are merely conjectures, (for no stars are now in the roof, nor are any said to have remained there so late as the reign of Queen Elizabeth), it may be allowable to propose another conjectural etymology, as plausible perhaps as any of them. It is well known, that, before the banishment of the Jews under Edward I. their contracts and obligations were denominated in our ancient records *starra* or *starrs*, from a corruption of the Hebrew word, *shetar*, a covenant. (Tovey's *Angl. Judaic.* 32. Selden. tit. of hon. ii. 34. *Uxor Ebraic.* i. 14.). These starrs, by an ordinance of Richard I. preserved by Hoveden, were commanded to be enrolled and deposited in chests

Blackstone's Comment. vol. iv. p. 266.

under three keys in certain places; one, and the most considerable, of which was in the king's exchequer at Westminster: and no starr was allowed to be valid, unless it were found in some of the said repositories. (*Memorand. in Scac' P. 6. Edw. I.* prefixed to Maynard's year-book of Edw. II. fol. 8. Madox hist. exch. c. vii. § 4, 5, 6.). The room at the exchequer, where the chests containing these starrs were kept, was probably called the *star-chamber*; and, when the Jews were expelled the kingdom, was applied to the use of the king's council, sitting in their judicial capacity. To confirm this, the first time the star-chamber is mentioned in any record, it is said to have been situated near the receipt of the exchequer at Westminster: (the king's council, his chancellor, treasurer, justices, and other sages, were assembled *en la chaumbre des esteilles pres la resceipt at Westminster. Claus.* 41 *Edw. III. m.* 13.). For in process of time, when the meaning of the Jewish *starrs* were forgotten, the word *star-chamber* was naturally rendered in law French, *la chaumbre des esteilles*, and in law Latin *camera stellata*; which continued to be the style in Latin till the dissolution of that court.

This was a court of very ancient original; but new-modelled by statutes 3 Hen. VII. c. 1. and 21 Henry VIII. c. 20. consisting of divers lords spiritual and temporal, being privy-counsellors, together with two judges of the courts of common law, without the intervention of any jury. Their jurisdiction extended legally over riots, perjury, misbehaviour of sheriffs, and other notorious misdemeanors, contrary to the laws of the land. Yet this was afterwards (as Lord Clarendon informs us) stretched "to the asserting of all proclamations and orders of state; to the vindicating of illegal commissions and grants of monopolies; holding for honourable that which pleased, and for just that which profited; and becoming both a court of law to determine civil rights, and a court of revenue to enrich the treasury: the council-table by proclamations enjoining to the people that which was not enjoined by the laws, and prohibiting that which was not prohibited; and the star-chamber, which consisted of the same persons in different rooms, censuring the breach and disobedience to those proclamations by very great fines, imprisonments, and corporal severities: so that any disrespect to any acts of state, or to the persons of statesmen, was in no time more penal, and the foundations of right never more in danger to be destroyed." For which reasons, it was finally abolished by statute 16 Car. I. c. 10. to the general joy of the whole nation. See *KING's-Bench.* There is in the British Museum (Harl. MSS. vol. i. N° 126.) a very full, methodical, and accurate account of the constitution and course of this court, compiled by William Hudson of Gray's Inn, an eminent practitioner therein. A short account of the same, with copies of all its process, may also be found in 18 Rym. Foed. 192, &c.

STAR-Board, the right side of the ship when the eye of the spectator is directed forward.

STAR-Fish. See ASTERIAS, HELMINTHOLOGY *Index*.

STAR-Shot, a gelatinous substance frequently found in fields, and supposed by the vulgar to have been produced from the meteor called a *falling-star*: but, in reality, is the half-digested food of herons, sea-mews, and

and the like birds; for thefe birds have been found when newly fhot, to difgorge a fubftance of the fame kind.

STAR-Stone, in *Natural Hiftory*, a name given to certain extraneous foffil ftones, in form of fhort, and commonly fomewhat crooked columns, compofed of feveral joints, each refembling the figure of a radiated ftar, with a greater or fmaller number of rays in the different fpecies: they are ufually found of about an inch in length, and of the thicknefs of a goofe-quill. Some of them have five angles or rays, and others only four; and in fome the angles are equidiftant, while in others they are irregularly fo: in fome alfo they are fhort and blunt, while in others they are long, narrow, and pointed; and fome have their angles very fhort and obtufe. The feveral joints in the fame fpecimen are ufually all of the fame thicknefs; this, however, is not always the cafe: but in fome they are larger at one end, and in others at the middle, than in any other part of the body; and fome fpecies have one of the rays bifid, fo as to emulate the appearance of a fix-rayed kind.

STAR-Thiftle. See CENTAUREA, } BOTANY *Index*.
STAR-Wort. See ASTER, } BOTANY *Index*.

STARCH, a fecula or fediment, found at the bottom of veffels wherein wheat has been fteeped in water, of which fecula, after feparating the bran from it, by paffing it through fieves, they form a kind of loaves, which being dried in the fun or an oven, is afterwards cut into little pieces, and fo fold. The beft ftarch is white, foft, and friable, and eafily broken into powder. Such as require fine ftarch, do not content themfelves, like the ftarchmen, with refufe wheat, but ufe the fineft grain. The procefs is as follows: The grain, being well cleaned, is put to ferment in veffels full of water, which they expofe to the fun while in its greateft heat; changing the water twice a-day, for the fpace of eight or twelve days, according to the feafon. When the grain burfts eafily under the finger, they judge it fufficiently fermented. The fermentation perfected, and the grain thus foftened, it is put, handful by handful, into a canvas-bag, to feparate the flour from the hufks; which is done by rubbing and beating it on a plank laid acrofs the mouth of an empty veffel that is to receive the flour.

As the veffels are filled with this liquid flour, there is feen fwimming at top a reddifh water, which is to be carefully fcummed off from time to time, and clean water is to be put in its place, which, after ftirring the whole together, is alfo to be ftrained through a cloth or fieve, and what is left behind put into the veffel with new water, and expofed to the fun for fome time. As the fediment thickens at the bottom, they drain off the water four or five times, by inclining the veffel, but without paffing it through the fieve. What remains at bottom is the ftarch, which is cut in pieces to get out, and left to dry in the fun. When dry, it is laid up for ufe.

The following mill, was invented by M. Baumé for grinding potatoes, with a view to extract ftarch from them.

He had a grater made of plate iron, in a cylindrical form (fig. 1.) about feven inches in diameter, and about eight inches high; the burs made by ftumping the holes are on the infide. This grater is fupported upon three feet AAA, made of flat iron bars, feven feet high,

Plate D. Fig. 1.

ftrongly rivetted to the grater; the bottom of each foot is bent horizontally, and has a hole in it which receives a fcrew, as at A, fig. 4. A little below the upper end of the three feet is fixed a crofs piece B (fig. 1. and 4.), divided into three branches, and rivetted to the feet. This crofs piece not only ferves to keep the feet at a pruper diftance from each other, and to prevent their bending; but the centre of it having a hole cut in it, ferves to fupport an axis or fpindle of iron, to be prefently defcribed.

The upper end of this cylindrical grater has a diverging border of iron C (fig. 1. 4. and 7.), about 10 inches in diameter at the top, and five inches in height.

Within this cylindrical grater is placed a fecond grater (fig. 2. and 3.), in the form of a cone, the point of which is cut off. The latter is made of thick plate iron, and the burs of the holes are on the outfide; it is fixed, with the broad end at the bottom, as in fig. 4. At the upper end of the cone is rivetted a fmall triangle, or crofs piece of iron, confifting of three branches D (fig. 2.), in the middle of which is made a fquare hole, to receive an axis or fpindle; to give more refiftance to this part of the cone, it is ftrengthened by means of a cap of iron E, which is fixed to the grater by means of rivets, and has alfo a fquare hole made in it, to let the axis pafs through.

Fig. 3. reprefents the fame cone feen in front; the bafe F has alfo a crofs piece of three branches, rivetted to a hoop of iron, which is fixed to the inner furface of the cone; the centre of this crofs piece has alfo a fquare hole for the paffage of the axis.

Fig. 5. is a fpindle or axis itfelf; it is a fquare bar of iron about 16 inches long, and more than half an inch thick; round at the bottom, and alfo towards the top, where it fits into the crofs piece I, fig. 7. and B, fig. 1. and 4.; in thefe pieces it turns round, and by them it is kept in its place. It muft be fquare at its upper extremity, that it may have a handle, about nine inches long, fixed to it, by means of which the conical grater is turned round. At G, (fig. 5.), a fmall hole is made through the axis, to receive a pin H, by means of which the conical grater is kept at its proper height within the cylindrical one.

Fig. 6. is a bird's-eye view, in which the mill is reprefented placed in an oval tub, like a bathing-tub. I is the fore-mentioned triangular iron crofs, fixed with fcrews to the fide of the tub; the centre of it has a round hole, for the axis of the mill to move in when it is ufed.

Fig. 7. reprefents the mill in the oval tub; it is placed at one end of it, that the other end may be left free for any operation to be performed in it which may be neceffary. A part of the tub is cut off, that the infide of it, and the manner of fixing the mill, may be feen. That the bottom of the tub may not be worn by the fcrews which pafs through the feet of the mill, a deal board, about an inch thick, and properly fhaped, is placed under the mill.

When we wifh to make ufe of this mill, it is to be fixed by the feet, in the manner already defcribed; it is alfo fixed at the top, by means of the crofs piece I, fig. 6. and 7. The tub is then to have water poured into it as high as K, and the top of the mill is to be filled with potatoes, properly wafhed and cut; the handle L is to be turned round, and the potatoes, after being ground

between

between the two graters, go out gradually at the lower part, being affifted by the motion produced in the water by the action of the mill.

To prepare ftarch from potatoes, fays M. Baumé, any quantity of thefe roots may be taken, and foaked in a tub of water for about an hour; they are afterwards to have their fibres and fhoots taken off, and then to be rubbed with a pretty ftrong brufh, that the earth, which is apt to lodge in the inequalities of their furface, may be entirely removed; as this is done, they are to be wafhed, and thrown into another tub full of clean water. When the quantity which we mean to make ufe of has been thus treated, thofe which are too large are to be cut into pieces about the fize of eggs, and thrown into the mill; that being already fixed in the oval tub, with the proper quantity of water: the handle is then turned round, and as the potatoes are grated they pafs out at the bottom of the mill. The pulp which collects about the mill muft be taken off from time to time with a wooden fpoon, and put afide in water.

When all the potatoes are ground, the whole of the pulp is to be collected in a tub, and mixed up with a great quantity of clean water. At the fame time, another tub, very clean, is to be prepared, on the brim of which are to be placed two wooden rails, to fupport a hair fieve, which muft not be too fine. The pulp and water are to be thrown into the fieve; the flour paffes through with the water, and frefh quantities of water are fucceffively to be poured on the remaining pulp, till the water runs through as clear as it is poured in. In this way we are to proceed till all the potatoes that were ground are ufed.

The pulp is commonly thrown away as ufelefs; but it fhould be boiled in water, and ufed as food for animals; for it is very nourifhing, and is about $\frac{4}{5}$ths of the whole quantity of potatoes ufed.

It is farther to be obferved that the liquor which has paffed through the fieve is turbid, and of a brownifh colour, on account of the extractive matter which is diffolved in it; it depofits, in the fpace of five or fix hours, the flour which was fufpended in it. When all the flour is fettled to the bottom, the liquor is to be poured off and thrown away, being ufelefs; a great quantity of very clean water is then to be poured upon the flour remaining at the bottom of the tub, which is to be ftirred up in the water, that it may be wafhed, and the whole is to ftand quiet till the day following. The flour will then be found to have fettled at the bottom of the tub; the water is again to be poured off as ufelefs, the flour wafhed in a frefh quantity of pure water, and the mixture paffed through a filk fieve pretty fine, which will retain any fmall quantity of pulp which may have paffed through the hair fieve. The whole muft once more be fuffered to ftand quiet till the flour is entirely fettled; if the water above it is perfectly clear and colourlefs, the flour has been fufficiently wafhed; but if the water has any fenfible appearances either of colour or of tafte, the flour muft be again wafhed, as it is abfolutely neceffary that none of the extractive matter be fuffered to remain.

When the flour is fufficiently wafhed, it may be taken out of the tub with a wooden fpoon; it is to be placed upon wicker frames covered with paper, and dried, properly defended from duft. When it is thoroughly dry, it is to be paffed through a filk fieve, that if any clotted lumps fhould have been formed they may be divided. It is to be kept in glafs-veffels ftopped with paper only.

A patent was granted in 1796 to Lord William Murray for his difcovery of a method by which ftarch may be extracted from horfe-chefnuts. It is as follows:

Take the horfe-chefnuts out of the outward green prickly hufks; and either by hand, with a knife, or other tool, or elfe with a mill adapted for that purpofe, very carefully pare off the brown rind, being particular not to leave the fmalleft fpeck, and to entirely eradicate the fprout or growth. Next take the nuts, and rafp, grate, or grind them fine into water, either by hand, or by a mill adapted for that purpofe. Wafh the pulp, which is thereby formed in this water, as clean as poffible, through a coarfe horfe-hair fieve; this again wafh through a finer fieve, and then again through a ftill finer, conftantly adding clean water, to prevent any ftarch from adhering to the pulp. The laft procefs is, to put it with a large quantity of water (about four gallons to a pound of ftarch) through a fine gauze, muflin, or lawn, fo as entirely to clear it of all bran or other impurities. As foon as it fettles, pour off the water; then mix it up with clean water, repeating this operation till it no longer imparts any green, yellow, or other colour to the water. Then drain it off till nearly dry, and fet it to bake, either in the ufual mode of baking ftarch, or elfe fpread out before a brifk fire; being very attentive to ftir it frequently to prevent its horning, that is to fay, turning to a pafte or jelly, which, on being dried, turns hard like horn. The whole procefs fhould be conducted as quickly as poffible.

Mention is here made of a mill which may be employed to grind the horfe-chefnuts; but it is not defcribed; perhaps the one defcribed above for grinding potatoes might anfwer the purpofe.

STARK, Dr William, known to the public by a volume containing Clinical and Anatomical Obfervations, with fome curious Experiments on Diet, was born at Manchefter in the month of July 1740; but the family from which he fprang was Scotch, and refpectable for its antiquity. His grandfather John Stark of Killermont was a covenanter; and having appeared in arms againft his fovereign at the battle of Bothwel bridge in the year 1679, became obnoxious to the government, and, to conceal himfelf, withdrew into Ireland. There is reafon to believe that he had not imbibed either the extravagant zeal or the favage manners of the political and religious party to which he adhered; for after refiding a few years in the country which he had chofen for the fcene of his banifhment, he married Elizabeth daughter of Thomas Stewart, Efq. of Balydrone in the north of Ireland; who, being defcended of the noble family of Galloway, would not probably have matched his daughter to fuch an exile as a ruthlefs fanatic of the laft century. By this lady Mr Stark had feveral children; and his fecond fon Thomas, who fettled at Manchefter as a wholefale linen-draper, and married Margaret Stirling, daughter of William Stirling, Efq. of Northwoodfide, in the neighbourhood of Glafgow, was the father of the fubject of this article. Another of his fons, the reverend John Stark, was minifter of Lecropt in Perthfhire; and it was under the care of this gentleman that our author received the rudiments of his education, which, when we confider the character of the mafter, Stark.

and reflect on the relation between him and his pupil, we may presume was calculated to store the mind of Dr Stark with those virtuous principles which influenced his conduct through life.

From Lecropt young Stark was sent to the university of Glasgow, where, under the tuition of the doctors Smith and Black, with other eminent masters, he learned the rudiments of science, and acquired that mathematical accuracy, that logical precision, and that contempt of hypotheses, with which he prosecuted all his future studies. Having chosen physic for his profession. he removed from the university of Glasgow to that of Edinburgh, where he was soon distinguished, and honoured with the friendship of the late Dr Cullen; a man who was not more eminently conspicuous for the superiority of his own genius, than quick-sighted in perceiving, and liberal in encouraging, genius in his pupils. Having finished his studies at Edinburgh, though he took there no degree, Mr Stark, in the year 1765, went to London, and devoted himself entirely to the study of physic and the elements of surgery; and looking upon anatomy as one of the principal pillars of both these arts, he endeavoured to complete with Dr Hunter what he had begun with Dr Monro; and under these two eminent professors he appears to have acquired a high degree of anatomical knowledge. He likewise entered himself about this time a pupil at St George's hospital; for being disgusted, as he often confessed, with the inaccuracy or want of candour observable in the generality of practical writers, he determined to obtain an acquaintance with diseases at a better school and from an abler master; and to have from his own experience a standard, by which he might judge of the experience of others. With what industry he prosecuted this plan, and with what success his labours were crowned, may be seen in a series of Clinical and Anatomical Observations, which were made by him during his attendance at the hospital, and were published after his death by his friend Dr Carmichael Smyth. These observations give the public no cause to complain of want of candour in their author; for whatever delicacy he may have observed, when relating the cases of patients treated by other physicians, he has related those treated by himself with the utmost impartiality. Whilst attending the hospital, he likewise employed himself in making experiments on the blood, and other animal fluids; and also in a course of experiments in chemical pharmacy; but though accounts of these experiments were left behind him, we believe they have not yet been given to the public.

In the year 1767 Mr Stark went abroad, and obtained the degree of M. D in the university of Leyden, publishing an inaugural dissertation on the dysentery. On his return to London, he recommenced his studies at the hospital; and when Dr Black was called to the chemical chair in Edinburgh, which he has long filled with so much honour to himself and credit to the university, Dr Stark was solicited by several members of the university of Glasgow to stand a candidate for their professorship of the theory and practice of physic, rendered vacant by Dr Black's removal to Edinburgh. This however Dr Stark declined, being influenced by the advice of his English friends, who wished to detain him in London, and having likewise some prospects of an appointment in the hospital.

In the mean time he had commenced (1769) a series of experiments on diet, which he was encouraged to undertake by Sir John Pringle and Dr Franklin, whose friendship he enjoyed, and from whom he received many hints respecting both the plan and its execution. These experiments, or rather the imprudent zeal with which he prosecuted them, proved, in the opinion of his friends, fatal to himself; for he began them on the 12th of July 1769 in perfect health and vigour, and from that day, though his health varied, it was seldom if ever good, till the 23d of February 1770, when he died, after suffering much uneasiness. His friend and biographer Dr Smyth thinks, that other causes, particularly chagrin and disappointment, had no small share in hastening his death; and as the Doctor was intimately acquainted with his character and disposition, his opinion is probably well-founded, though the pernicious effects of the experiments are visible in Dr Stark's own journal. When he entered upon them, the weight of his body was 12 stone 3 lb. avoirdupois, which in a very few days was reduced to 11 stone 10 lb. 8 oz.: and though some kinds of food increased it, by much the greater part of what he used had a contrary effect, and it continued on the whole to decrease till the day of his death. This indeed can excite no wonder. Though the professed object of his experiments was to prove that a *pleasant* and varied diet is equally conducive to health with a more strict and simple one, most of the dishes which he ate during these experiments were neither pleasant nor simple, but compounds, such as every stomach must nauseate. He began with *bread* and *water;* from which he proceeded to *bread*, *water*, and *sugar;* then to *bread*, *water*, and *oil of olives;* then to *bread* and *water* with *milk;* afterwards he tried *bread* and *water* with *roasted goose; bread* and *water* with *boiled beef; stewed lean of beef* with the *gravy* and *water* without bread; *stewed lean of beef* with the *gravy*, *oil* of *fat* or *suet* and *water; flour*, *oil of suet*, *water* and *salt; flour*, *water*, and *salt;* and a number of others infinitely more disagreeable to the stomach than even these, such as *bread, fat of bacon ham*, *infusion of tea* with *sugar;* and *bread* or *flour* with *honey* and the infusion of *rosemary*. But though we consider Dr Stark's experiments as whimsical, it cannot be denied that they indicate eccentricity of genius in the person who made them; and such of our readers as think genius hereditary, may perhaps be of opinion, that he derived a ray from the celebrated NAPIER the inventor of the logarithms, who was his ancestor by both parents. At any rate, these experiments, of which a full account is given in the same volume with his clinical and anatomical observations, display an uncommon degree of fortitude, perseverance, self-denial, and zeal for the promoting of useful knowledge in their author; and with respect to his moral character, we believe it is with great justice that Dr Smyth compares him to Cato, by applying to him what was said of that virtuous Roman by Sallust—" Non divitiis cum divite, neque factione cum factioso; sed cum strenuo virtute, cum modesto pudore, cum innocente abstinentia certabat; esse, quam videri, bonus malebat * "

* *Bellum Catilinarium.*

Stark || Starlings.

STARLING. See STURNUS, ORNITHOLOGY *Index*.

STARLINGS, or STERLINGS, the name given to the strong pieces of timber which were driven into the bed of the river to protect the piles, on the top of which were laid the flat beams upon which were built the

the bases of the stone piers that support the arches of London bridge. In general, starlings are large piles placed on the outside of the foundation of the piers of bridges, to break the force of the water, and to protect the stone work from injury by floating ice. They are otherwise called *jetts*, and their place is often supplied by large stones thrown at random round the piers of bridges, as may be seen at Stirling bridge when the river is low; and as was done by Mr Smeaton's direction round the piers of the centre arch of London bridge, when it was thought in danger of being undermined by the current.

STATE OF A CONTROVERSY. See ORATORY, Part I. N° 14.

STATES, or ESTATES, a term applied to several orders or classes of people assembled to consult of matters for the public good.

Thus states-generals, in the old government of Holland, is the name of an assembly consisting of the deputies of the seven United Provinces. These were usually 30 in number, some provinces sending two, others more; and whatever resolution the states-general took was confirmed by every province, and by every city and republic in that province, before it had the force of a law. The deputies of each province, of what number soever they were, had only one voice, and were esteemed as but one person, the votes being given by provinces. Each province presided in the assembly in its turn, according to the order settled among them. Guelderland presided first, then Holland, &c.

States of Holland were the deputies of eighteen cities, and one representative of the nobility, constituting the states of the province of Holland: the other provinces had likewise their states, representing their sovereignty; deputies from which made what was called the states-general. In an assembly of the states of a particular province, one dissenting voice prevented their coming to any resolution.

STATICE, THRIFT, a genus of plants belonging to the class of pentandria, and order of pentagynia; and in the natural system ranging under the 48th order, *Aggregatae*. See BOTANY *Index*.

STATICS, a term which the modern improvements in knowledge have made it necessary to introduce into physico-mathematical science. It was found convenient to distribute the doctrines of universal mechanics into two classes, which required both a different mode of consideration and different principles of reasoning.

Till the time of Archimedes little science of this kind was possessed by the ancients, from whom we have received the first rudiments. His investigation of the centre of gravity, and his theory of the lever, are the foundations of our knowledge of common mechanics; and his theory of the equilibrium of floating bodies contains the greatest part of our hydrostatical knowledge. But it was as yet limited to the simplest cases; and there were some in which Archimedes was ignorant, or was mistaken. The marquis Guido Ubuldi, in 1578, published his theory of mechanics, in which the doctrines of Archimedes were well explained and considerably augmented. Stevinus, the celebrated Dutch engineer, published about 20 years after an excellent system of mechanics, containing the chief principles which now form the science of equilibrium among solid bodies. In particular, he gave the theory of inclined planes, which was unknown to the ancients, though it is of the very first importance in almost every machine. He even states in the most express terms the principle afterwards made the foundation of the whole of mechanics, and published as a valuable discovery by Varignon, viz. that three forces, whose directions and intensities are as the sides of a triangle, balance each other. His theory of the pressure of fluids, or hydrostatics, is no less estimable, including every thing that is now received as a leading principle in the science. When we consider the ignorance, even of the most learned, of that age, in mechanical or physico-mathematical knowledge, we must consider these performances as the works of a great genius; and we regret that they are so little known, being lost in a crowd of good writings on those subjects which appeared soon after.

Hitherto the attention had been turned entirely to equilibrium, and the circumstances necessary for producing it. Mechanicians indeed saw, that the energy of a machine might be somehow measured by the force which could be opposed or overcome by its intervention: but they did not remark, that the force which prevented its motion, but did no more than prevent it, was an *exact* measure of its energy, because it was in immediate equilibrio with the pressure exerted by that part of the machine with which it was connected. If this opposed force was less, or the force acting at the other extremity of the machine was greater, the mechanicians knew that the machine would move, and that work would be performed; but what would be the rate of its motion or its performance, they hardly pretended to conjecture. They had not studied the action of moving forces, nor conceived what was done when motion was communicated.

The great Galileo opened a new field of speculation in his work on Local Motion. He there considers a change of motion as the indication and exact and adequate measure of a moving force; and he considers every kind of pressure as competent to the production of such changes.—He contented himself with the application of this principle to the motion of bodies by the action of gravity, and gave the theory of projectiles, which remains to this day without change, and only improved by considering the changes which are produced in it by the resistance of the air.

Sir Isaac Newton took up this subject nearly as Galileo had left it. For, if we except the theory of the centrifugal forces arising from rotation, and the theory of pendulums, published by Huygens, hardly any thing had been added to the science of motion. Newton considered the subject in its utmost extent; and in his mathematical principles of natural philosophy he considers every conceivable variation of moving force, and determines the motion resulting from its action.—His first application of these doctrines was to explain the celestial motions; and the magnificence of this subject caused it to occupy for a while the whole attention of the mathematicians. But the same work contained propositions equally conducive to the improvement of common mechanics, and to the complete understanding of the mechanical actions of bodies. Philosophers began to make these applications also. They saw that every kind of work which is to be performed by a machine may be considered abstractedly as a retarding force; that the impulse of water or wind, which are employed as moving powers, Statics ‖ Statistics.

act by means of pressures which they exert on the impelled point of the machine; and that the machine itself may be considered as an assemblage of bodies moveable in certain limited circumstances, with determined directions and proportions of velocity. From all these considerations resulted a general abstract condition of a body acted on by known powers. And they found, that after all conditions of equilibrium were satisfied, there remains a surplus of moving force. They could now state the motion which will ensue, the new resistance which this will excite, the additional power which this will absorb; and they at last determined a new kind of equilibrium, not thought of by the ancient mechanicians, between the resistance to the machine performing work and the moving power, which exactly balance each other, and is indicated, not by the *rest*, but by the *uniform motion* of the machine.—In like manner, the mathematician was enabled to calculate that precise motion of water which would completely absorb, or, in the new language, balance the superiority of pressure by which water is forced through a sluice, a pipe, or canal, with a constant velocity.

Thus the general doctrines of motion came to be considered in two points of view, according as they balanced each other in a state of rest or of uniform motion. These two ways of considering the same subject required both different principles and a different manner of reasoning. The first has been named *statics*, as expressing that rest which is the test of this kind of equilibrium. The second has been called DYNAMICS or UNIVERSAL MECHANICS, because the different kinds of motion are characteristic of the powers or forces which produce them. A knowledge of both is indispensably necessary for acquiring any useful practical knowledge of machines; and it was ignorance of the doctrines of accelerated and retarded motions which made the progress of practical mechanical knowledge so very slow and imperfect. The mechanics, even of the moderns, before Galileo, went no further than to state the proportion of the power and resistance which would be balanced by the intervention of a given machine, or the proportion of the parts of a machine by which two known forces may balance each other. This view of the matter introduced a principle, which even Galileo considered as a mechanical axiom, viz. that *what is gained in force by means of a machine is exactly compensated by the additional time which it obliges us to employ*. This is false in every instance, and not only prevents improvement in the construction of machines, but leads us into erroneous maxims of construction. The true principles of dynamics teach us, that there is a certain proportion of the machine, dependent on the kind and proportion of the power and resistance, which enables the machine to perform the greatest possible work.

It is highly proper therefore to keep separate these two ways of considering machines, that both may be improved to the utmost, and then to blend them together in every practical discussion.

Statics therefore is preparatory to the proper study of mechanics; but it does not hence derive all its importance. It is the sole foundation of many useful parts of knowledge. This will be best seen by a brief enumeration.

1. It comprehends all the doctrines of the excitement and propagation of pressure through the parts of solid bodies, by which the energies of machines are produced. A pressure is exerted on the impelled point of a machine, such as the float-boards or buckets of a mill-wheel. This excites a pressure at the pivots of its axle, which act on the points of support. This must be understood, both as to direction and intensity, that it may be effectually resisted. A pressure is also excited at the acting tooth of the cog-wheel on the same axle, by which it urges round another wheel, exciting similar pressures on its pivots and on the acting tooth perhaps of a third wheel.—Thus a pressure is ultimately excited in the working point of the machine, perhaps a wiper, which lifts a heavy stamper, to let it fall again on some matter to be pounded. Now statics teaches us the intensities and direction of all those pressures, and therefore how much remains at the working point of the machine unbalanced by resistance.

2. It comprehends every circumstance which influences the stability of heavy bodies; the investigation and properties of the centre of gravity; the theory of the construction of arches, vaults, and domes; the attitudes of animals.

3. The strength of materials, and the principles of construction, so as to make the proper adjustment of strength and strain in every part of a machine, edifice, or structure of any kind. Statics therefore furnishes us with what may be called *a theory of carpentry*, and gives us proper instructions for framing floors, roofs, centres, &c.

4. Statics comprehends the whole doctrine of the pressure of fluids, whether liquid or aeriform, whether arising from their weight or from any external action. Hence therefore we derive our knowledge of the stability of ships, or their power of maintaining themselves in a position nearly upright, in opposition to the action of the wind on their sails. We learn on what circumstances of figure and stowage this quality depends, and what will augment or diminish it.

Very complete examples will be given in the remaining part of this work of the advantages of this separate consideration of the condition of a machine at rest and in working motion; and in what yet remains to be delivered of the hydraulic doctrines in our account of *WATER-Works* in general, will be perceived the propriety of stating apart the equilibrium which is indicated by the uniform motion of the fluid. The observations too which we have to make on the strength of the materials employed in our edifices or mechanical structures, will be examples of the investigation of those powers, pressures, or strains, which are excited in all their parts.

STATIONARY, in *Astronomy*, the state of a planet when, to an observer on the earth, it appears for some time to stand still, or remain immoveable in the same place in the heavens. For as the planets, to such an observer, have sometimes a progressive motion, and sometimes a retrograde one, there must be some point between the two where they must appear stationary.

STATISTICS, a word lately introduced to express a view or survey of any kingdom, county, or parish.

A Statistical view of Germany was published in 1790 by Mr B. Clarke: giving an account of the imperial and territorial constitutions, forms of government, legislation, administration of justice, and of the ecclesiastical state;

ſtate; with a ſketch of the character and genius of the Germans; a ſhort inquiry into the ſtate of their trade and commerce; and giving a diſtinct view of the dominions, extent, number of inhabitants to a ſquare mile; chief towns, with their ſize and population; revenues, expences, debts, and military ſtrength of each ſtate. In Pruſſia, in Saxony, Sardinia, and Tuſcany, attempts have alſo been made to draw up ſtatiſtical accounts; but they were done rather with a view of aſcertaining the preſent ſtate of theſe countries, than as the means of future improvement.

A grand and extenſive work of this kind, founded on a judicious plan, conducted by the moſt patriotic and enlightened motives, and drawn up from the communications of the whole body of the clergy, was undertaken in Scotland in the year 1790 by Sir John Sinclair of Ulbſter, one of the moſt uſeful members of his country. Many praiſes are heaped upon genius and learning; but to genius and learning no applauſe is due, except when exerted for the benefit of mankind: but gratitude and praiſe is due to him whoſe talents ſhine only in great undertakings, whoſe happineſs ſeems to conſiſt in partriotic exertions, and whoſe judgement is uniformly approved by his ſucceſs. A work of this kind, ſo important in its object, ſo comprehenſive in its range, ſo judicious in its plan, and drawn up by more than 900 men of literary education, many of them men of great genius and learning, muſt be of immenſe value. It was completed about 1799, in 21 volumes 8vo.

The great object of this work is to give an accurate view of the ſtate of the country, its agriculture, its manufactures, and its commerce; the means of improvement, of which they are reſpectively capable; the amount of the population of a ſtate, and the cauſes of its increaſe or decreaſe; the manner in which the territory of a country is poſſeſſed and cultivated; the nature and amount of the various productions of the ſoil; the value of the perſonal wealth or ſtock of the inhabitants, and how it can be augmented; the diſeaſes to which the people are ſubject, their cauſes and their cure; the occupations of the people; where they are entitled to encouragement, and where they ought to be ſuppreſſed; the condition of the poor, the beſt mode of maintaining them, and of giving them employment; the ſtate of ſchools, and other inſtitutions, formed for purpoſes of public utility; the ſtate of the villages and towns, and the regulations beſt calculated for their police and good government; the ſtate of the manners, the morals, and the religious principles of the people, and the means by which their temporal and eternal intereſts can beſt be promoted.

To ſuch of our readers as have not an opportunity of peruſing this national work, or of examining its plan, we will preſent the ſcheme for the ſtatiſtical account of a parochial diſtrict which Sir John Sinclair publiſhed for the conſideration of the clergy, and which has been generally followed by them, though often with great improvements.

The name of the pariſh and its origin; ſituation and extent of the pariſh; number of acres; deſcription of the ſoil and ſurface; nature and extent of the ſea coaſt; lakes, rivers, iſlands, hills, rocks, caves, wood, orchards, &c.; climate and diſeaſes; inſtances of longevity; ſtate of property; number of proprietors; number of reſiding proprietors; mode of cultivation; implements of huſbandry; manures; ſeedtime and harveſt; remarkable inſtances of good and bad ſeaſons; quantity and value of each ſpecies of crop; total value of the whole produce of the diſtrict; total quantity of grain and other articles conſumed in the pariſh; wages and price of labour; ſervices, whether exacted or aboliſhed; commerce; manufactures; manufacture of kelp, its amount, and the number of people employed in it; fiſheries; towns and villages; police; inns and alehouſes; roads and bridges; harbours, ferries, and their ſtate; number of ſhips and veſſels; number of ſeamen; ſtate of the church; ſtipend, manſe, glebe, and patron; number of poor; parochial funds, and the management of them; ſtate of the ſchools, and number of ſcholars; ancient ſtate of population; cauſes of its increaſe or decreaſe; number of families; exact amount of the number of ſouls now living; diviſion of the inhabitants; 1. By the place of their birth; 2. By their ages; 3. By their religious perſuaſions; 4. By their occupations and ſituation in life; 5. By their reſidence, whether in town, village, or in the country; number of houſes; number of uninhabited houſes; number of dove-cots, and to what extent they are deſtructive to the crops; number of horſes, their nature and value; number of cattle, their nature and value; number of ſheep, their nature and value; number of ſwine, their nature and value; minerals in general; mineral ſprings; coal and fuel; eminent men; antiquities; parochial records; miſcellaneous obſervations; character of the people; their manners, cuſtoms, ſtature, &c.; advantages and diſadvantages; means by which their ſituation could be meliorated.

If ſimilar ſurveys (ſays the public-ſpirited editor of this work) were inſtituted in the other kingdoms of Europe, it might be the means of eſtabliſhing, on ſure foundations, the principles of that moſt important of all ſciences, viz. political or ſtatiſtical philoſophy; that is, the ſcience, which, in preference to every other, ought to be held in reverence. No ſcience can furniſh, to any mind capable of receiving uſeful information, ſo much real entertainment, none can yield ſuch important hints for the improvement of agriculture, for the extenſion of commercial induſtry, for regulating the conduct of individuals, or for extending the proſperity of the ſtate; none can tend ſo much to promote the general happineſs of the ſpecies.

STATIUS, Publius Papinius, a celebrated Latin poet of the firſt century, was born at Naples, and was the ſon of Statius, a native of Epirus, who went to Rome to teach poetry and eloquence, and had Domitian for his ſcholar. Statius the poet alſo obtained the favour and friendſhip of that prince; and dedicated to him his Thebais and Achilleis; the firſt in twelve books, and the laſt in two. He died at Naples about the year 100. Beſides the above poems, there are alſo ſtill extant his *Sylvæ*, in five books; the ſtyle of which is purer, more agreeable, and more natural, than that of his Thebais and Achilleis.

STATUARY, a branch of ſculpture, employed in the making of ſtatues. See Sculpture and the next article.

Statuary is one of thoſe arts wherein the ancients ſurpaſſed the moderns; and indeed it was much more popular, and more cultivated, among the former than the latter. It is diſputed between ſtatuary and painting, which of the two is the moſt difficult and the moſt artful.

Statue.

Statuary is alſo uſed for the artificer who makes ſtatues. Phidias was the greateſt ſtatuary among the ancients, and Michael Angelo among the moderns.

STATUE, is defined to be a piece of ſculpture in full relievo, repreſenting a human figure. Daviler more ſcientifically defines ſtatue a repreſentation, in high relievo and inſulate, of ſome perſon diſtinguiſhed by his birth, merit, or great actions, placed as an ornament in a fine building, or expoſed in a public place, to preſerve the memory of his worth. In Greece one of the higheſt honours to which a citizen could aſpire was to obtain a ſtatue.

Statues are formed with the chiſel, of ſeveral matters, as ſtone, marble, plaſter, &c. They are alſo caſt of various kinds of metal, particularly gold, ſilver, braſs, and lead. For the method of caſting ſtatues, ſee the article *FOUNDERY of Statues*.

Statues are uſually diſtinguiſhed into four general kinds. The firſt are thoſe leſs than the life; of which kind we have ſeveral ſtatues of great men, of kings, and of gods themſelves. The ſecond are thoſe equal to the life; in which manner it was that the ancients, at the public expence, uſed to make ſtatues of perſons eminent for virtue, learning, or the ſervices they had done. The third are thoſe that exceed the life; among which thoſe that ſurpaſſed the life once and a half were for kings and emperors; and thoſe double the life, for heroes. The fourth kind were thoſe that exceeded the life twice, thrice, and even more, and were called *coloſſuſes*. See COLOSSUS.

Every ſtatue reſembling the perſon whom it is intended to repreſent, is called *ſtatua iconica*. Statues acquire various other denominations. 1. Thus, allegorical ſtatue is that which, under a human figure, or other ſymbol, repreſents ſomething of another kind; as a part of the earth, a ſeaſon, age, element, temperament, hour, &c. 2. Curule ſtatues, are thoſe which are repreſented in chariots drawn by bigæ or quadrigæ, that is, by two or four horſes; of which kind there were ſeveral in the circuſes, hippodromes, &c. or in cars, as we ſee ſome, with triumphal arches on antique medals. 3. Equeſtrian ſtatue, that which repreſents ſome illuſtrious perſon on horſeback, as that famous one of Marcus Aurelius at Rome; that of King Charles I. at Charing-croſs; King George II. in Leiceſter Square, &c. 4. Greek ſtatue, denotes a figure that is naked and antique; it being in this manner the Greeks repreſented their deities, athletæ of the olympic games, and heroes; the ſtatues of heroes were particularly called *Achillean ſtatues*, by reaſon of the great number of figures of Achilles in moſt of the cities of Greece. 5. Hydraulic ſtatue, is any figure placed as an ornament of a fountain or grotto, or that does the office of a *jet d'eau*, a cock, ſpout, or the like, by any of its parts, or by any attribute it holds: the like is to be underſtood of any animal ſerving for the ſame uſe. 6. Pedeſtrian ſtatue, a ſtatue ſtanding on foot; as that of King Charles II. in the Royal Exchange, and of King James II. in the Privy-Gardens. 7. Roman ſtatue, is an appellation given to ſuch as are clothed, and which receive various names from their various dreſſes. Thoſe of emperors, with long gowns over their armour, were called *ſtatuæ paludatæ*: thoſe of captains and cavaliers, with coats of arms, *thoracatæ*; thoſe of ſoldiers with cuiraſſes, *loricatæ*, thoſe of ſenators and augurs, *trabeatæ*; thoſe of magiſtrates with long robes, *togatæ*; thoſe of the people with a plain tunica, *tunicatæ*; and, laſtly, thoſe of women with long trains, *ſtolatæ*.

Statue ‖ Steam.

In repairing a ſtatue caſt in a mould, they touch it up with a chiſel, graver, or other inſtrument, to finiſh the places which have not come well off: they alſo clear off the barb, and what is redundant in the joints and projectures.

STATURE. See DWARF and GIANT.

STATUTE, in its general ſenſe, ſignifies a law, ordinance, decree, &c. See LAW, &c.

STATUTE, in our laws and cuſtoms, more immediately ſignifies an act of parliament made by the three eſtates of the realm; and ſuch ſtatutes are either general, of which the courts at Weſtminſter muſt take notice without pleading them; or they are ſpecial and private, which laſt muſt be pleaded.

STAVESACRE, a ſpecies of DELPHINIUM, which ſee, BOTANY *Index*.

STAY, a large ſtrong rope employed to ſupport the maſt on the fore part, by extending from its upper end towards the fore part of the ſhip, as the ſhrouds are extended to the right and left, and behind it. See MAST, RIGGING, and SHROUD.

The ſtay of the fore-maſt, which is called the *fore-ſtay*, reaches from the maſt-head towards the bowſprit end: the main ſtay extends over the forecaſtle to the ſhip's ſtem; and the mizen-ſtay is ſtretched down to that part of the main-maſt which lies immediately above the quarter-deck: the fore-top-maſt-ſtay comes alſo to the end of the bowſprit, a little beyond the fore-ſtay: the main-top-maſt ſtay is attached to the head or hounds of the fore-maſt; and the mizen-top-maſt ſtay comes alſo to the hounds of the main-maſt: the fore-top-gallant ſtay comes to the outer end of the jib-boom; and the main-top-gallant ſtay is extended to the head of the fore-top-maſt.

STAY-Sail, a ſort of triangular ſail extended upon a ſtay. See SAIL.

1 Definition.

STEAM, is the name given in our language to the viſible moiſt vapour which ariſes from all bodies which contain juices eaſily expelled from them by heats not ſufficient for their combuſtion. Thus we ſay, the ſteam of boiling water, of malt, of a tan-bed, &c. It is diſtinguiſhed from ſmoke by its not having been produced by combuſtion, by not containing any ſoot, and by its being condenſible by cold into water, oil, inflammable ſpirits, or liquids compoſed of theſe.

2 Appears like a white cloud

We ſee it riſe in great abundance from bodies when they are heated, forming a white cloud, which diffuſes itſelf and diſappears at no very great diſtance from the body from which it was produced. In this caſe the ſurrounding air is found loaded with the water or other juices which ſeem to have produced it, and the ſteam ſeems to be completely ſoluble in air, as ſalt is in water, compoſing while thus united a tranſparent elaſtic fluid.

3 when diſſeminated in air.

But in order to its appearance in the form of an opaque white cloud, the mixture with or diſſemination in air ſeems abſolutely neceſſary. If a tea-kettle boils violently, ſo that the ſteam is formed at the ſpout in great abundance, it may be obſerved, that the viſible cloud is not formed at the very mouth of the ſpout, but at a ſmall diſtance before it, and that the vapour is perfectly tranſparent at its firſt emiſſion. This is rendered ſtill more evident by fitting to the ſpout of the tea-kettle

Steam.

tea-kettle a glaſs pipe of any length, and of as large a diameter as we pleaſe. The ſteam is produced as copiouſly as without this pipe, but the vapour is tranſparent through the whole length of the pipe. Nay, if this pipe communicate with a glaſs veſſel terminating in another pipe, and if the veſſel be kept ſufficiently hot, the ſteam will be as abundantly produced at the mouth of this ſecond pipe as before, and the veſſel will be quite tranſparent. The viſibility therefore of the matter which conſtitutes the ſteam is an accidental or extraneous circumſtance, and requires the admixture with air; yet this quality again leaves it when united with air by ſolution. It appears therefore to require a *diſſemination* in the air. The appearances are quite agreeable to this notion: for we know that one perfectly tranſparent body, when minutely divided and diffuſed among the parts of another tranſparent body, but not diſſolved in it, makes a maſs which is viſible. Thus oil beaten up with water makes a white opaque maſs.

4. Is again converted into water by cold.

In the mean time, as ſteam is produced, the water gradually waſtes in the tea kettle, and will ſoon be totally expended, if we continue it on the fire. It is reaſonable therefore to ſuppoſe, that this ſteam is nothing but water changed by heat into an aerial or elaſtic form. If ſo, we ſhould expect that the privation of this heat would leave it in the form of water again. Accordingly this is fully verified by experiment; for if the pipe fitted to the ſpout of the tea kettle be ſurrounded with cold water, no ſteam will iſſue, but water will continually trickle from it in drops: and if the proceſs be conducted with the proper precautions, the water which we thus obtain from the pipe will be found equal in quantity to that which diſappears from the tea-kettle.

5 Its appearances explained,

This is evidently the common proceſs for diſtilling; and the whole appearances may be explained by ſaying, that the water is converted by heat into an elaſtic vapour, and that this, meeting with colder air, imparts to it the heat which it carried off as it aroſe from the heated water, and being deprived of its heat it is again water. The particles of this water being vaſtly more remote from each other than when they were in the tea-kettle, and thus being diſſeminated in the air, become viſible, by reflecting light from their anterior and poſterior ſurfaces, in the ſame manner as a tranſparent ſalt becomes viſible when reduced to a fine powder. This diſſeminated water being preſented to the air in a very extended ſurface, is quickly diſſolved by it, as pounded ſalt is in water, and again becomes a tranſparent fluid, but of a different nature from what it was before, being no longer convertible into water by depriving it of its heat.

6 and the cauſe of its converſion, by Dr Black's diſcovery of latent heat.

Accordingly this opinion, or ſomething very like it, has been long entertained. Muſchenbroeck expreſsly ſays, that the water in the form of vapour carries off with it all the heat which is continually thrown in by the fuel. But Dr Black was the firſt who attended minutely to the whole phenomena, and enabled us to form diſtinct notions of the ſubject. He had diſcovered that it was not ſufficient for converting ice into water that it be raiſed to that temperature in which it can no longer remain in the form of ice. A piece of ice of the temperature 32° of Fahrenheit's thermometer will remain a very long while in air of the temperature 50° before it be all melted, remaining all the while of the temperature 32°, and therefore continually abſorbing heat from the ſurrounding air. By comparing the time in which the ice had its temperature changed from 28° to 32° with the ſubſequent time of its complete liquefaction, he found that it abſorbed about 130 or 140 times as much heat as would raiſe its temperature one degree; and he found that one pound of ice, when mixed with one pound of water 140 degrees warmer, was juſt melted, but without riſing in its temperature above 32°. Hence he juſtly concluded, that water differed from ice of the ſame temperature by containing, as a conſtituent ingredient, a great quantity of fire, or of the cauſe of heat, united with it in ſuch a way as not to quit it for another colder body, and therefore ſo as not to go into the liquor of the thermometer and expand it. Conſidered therefore as the poſſible cauſe of heat, it was latent, which Dr Black expreſſed by the abbreviated term LATENT HEAT. If any more heat was added to the water it was not latent, but would readily quit it for the thermometer, and, by expanding the thermometer, would ſhow what is the degree of this *redundant* heat, while fluidity alone is the indication of the *combined* and latent heat.

Dr Black, in like manner, concluded, that in order to convert water into an elaſtic vapour, it was neceſſary, not only to increaſe its uncombined heat till its temperature is 212°, in which ſtate it is juſt ready to become elaſtic; but alſo to pour into it a great quantity of fire, or the cauſe of heat, which combines with every particle of it, ſo as to make it repel, or to recede from, its adjoining particles, and thus to make it a particle of an elaſtic fluid. He ſuppoſed that this additional heat might be combined with it ſo as not to quit it for the thermometer; and therefore ſo as to be in a latent ſtate, having elaſtic fluidity for its ſole indication.

7 The temperature at which it is produced, and the quantity of heat which it abſorbs.

This opinion was very conſiſtent with the phenomenon of boiling off a quantity of water. The application of heat to it cauſes it gradually to riſe in its temperature till it reaches the temperature 212°. It then begins to ſend off elaſtic vapour, and is ſlowly expended in this way, continuing all the while of the ſame temperature. The ſteam alſo is of no higher temperature, as appears by holding a thermometer in it. We muſt conclude that this ſteam contains all the heat which is expended in its formation. Accordingly the ſcalding power of ſteam is well known; but it is extremely difficult to obtain preciſe meaſures of the quantity of heat abſorbed by water during its converſion into ſteam. Dr Black endeavoured to aſcertain this point, by comparing the time of raiſing its temperature a certain number of degrees with the time of boiling it off by the ſame external heat; and he found that the heat latent in ſteam, which balanced the preſſure of the atmoſphere, was not leſs than 800 degrees. He alſo directed Dr Irvine of Glaſgow to the form of an experiment for meaſuring the heat actually extricated from ſuch ſteam during its condenſation in the refrigeratory of a ſtill, which was found to be not leſs than 774 degrees. Dr Black was afterwards informed by Mr Watt, that a courſe of experiments, which he had made in each of theſe ways with great preciſion, determined the latent heat of ſteam under the ordinary preſſure of the atmoſphere to be about 948 or 950 degrees. Mr Watt alſo found that water would diſtil with great eaſe

Steam.

in vacuo when of the temperature 70°; and that in this caſe the latent heat of the ſteam is not leſs than 1200 or 1300 degrees: and a train of experiments, which he had made by diſtilling in different temperatures, made him conclude that the ſum of the ſenſible and latent heats is a conſtant quantity. This is a curious and not an improbable circumſtance; but we have no information of the particulars of theſe experiments. The concluſion evidently preſuppoſes a knowledge of that particular temperature in which the water has no heat; but this is a point which is ſtill *ſub judice*.

8 Steam, by being combined with heat, becomes elaſtic and light,

This converſion of liquids (for it is not confined to water, but obtains alſo in ardent ſpirits, oils, mercury, &c.) is the cauſe of their boiling. The heat is applied to the bottom and ſides of the veſſel, and gradually accumulates in the fluid, in a ſenſible ſtate, uncombined, and ready to quit it and to enter into any body that is colder, and to diffuſe itſelf between them. Thus it enters into the fluid of a thermometer, expands it, and thus gives us the indication of the degree in which it has been accumulated in the water; for the thermometer ſwells as long as it continues to abſorb ſenſible heat from the water: and when the ſenſible heat in both is in equilibrio, in a proportion depending on the nature of the two fluids, the thermometer riſes no more, becauſe it abſorbs no more heat or fire from the water; for the particles of water which are in immediate contact with the bottom, are now (by this gradual expanſion of liquidity) at ſuch diſtance from each other, that their laws of attraction for each other and for heat are totally changed. Each particle either no longer attracts, or perhaps it repels its adjoining particle, and now accumulates round itſelf a great number of the particles of heat, and forms a particle of elaſtic fluid, ſo related to the adjoining new formed particles, as to repel them to a diſtance at leaſt a hundred times greater than their diſtances in the ſtate of water. Thus a maſs of elaſtic vapour of ſenſible magnitude is formed. Being at leaſt ten thouſand times lighter than an equal bulk of water, it muſt riſe up through it, as a cork would do, in form of a tranſparent ball or bubble, and getting to the top, it diſſipates, filling the upper part of the veſſel with vapour or ſteam. Thus, by toſſing the liquid into bubbles, which are produced all over the bottom and ſides of the veſſel, it produces the phenomenon of ebullition or boiling. Obſerve, that during its paſſage up through the water, it is not changed or condenſed; for the ſurrounding water is already ſo hot that the ſenſible or uncombined heat in it, is in equilibrio with that in the vapour, and therefore it is not diſpoſed to abſorb any of that heat which is combined as an ingredient of this vapour, and gives it its elaſticity. For this reaſon, it happens that water will not boil till its whole maſs be heated up to 212°; for if the upper part be colder, it robs the riſing bubble of that heat which is neceſſary for its elaſticity, ſo that it immediately collapſes again, and the ſurface of the water remains ſtill. This may be perceived by holding water in a Florence flaſk over a lamp or choffer. It will be obſerved, ſome time before the real ebullition, that ſome bubbles are formed at the bottom, and get up a very little way, and then diſappear. The diſtances which they reach before collapſing increaſe as the water continues to warm farther up the maſs, till at laſt it breaks out into boiling. If the handle of a tea-kettle be graſped with the hand, a tremor will be felt for ſome little time before boiling, ariſing from the little ſucceſſions which are produced by the collapſing of the bubbles of vapour. This is much more violent, and is really a remarkable phenomenon, if we ſuddenly plunge a lump of red hot iron into a veſſel of cold water, taking care that no red part be near the ſurface. If the hand be now applied to the ſide of the veſſel, a moſt violent tremor is felt, and ſometimes ſtrong thumps: theſe ariſe from the collapſing of very large bubbles. If the upper part of the iron be too hot, it warms the ſurrounding water ſo much, that the bubbles from below come up through it uncondenſed, and produce ebullition without this ſucceſſion. The great reſemblance of this tremor to the feeling which we have during the ſhock of an earthquake has led many to ſuppoſe that theſe laſt are produced in the ſame way, and their hypotheſis, notwithſtanding the objections which we have elſewhere ſtated to it, is by no means unfeaſible.

9 and produces the phenomenon of boiling.

10 The noiſe obſerved in the boiling of a tea-kettle explained.

It is owing to a ſimilar cauſe that violent thumps are ſometimes felt on the bottom of a tea-kettle, eſpecially one which has been long in uſe. Such are frequently cruſted on the bottom with a ſtony concretion. This ſometimes is detached in little ſcales. When one of theſe is adhering by one end to the bottom, the water gets between them in a thin film. Hence it may be heated conſiderably above the boiling temperature, and it ſuddenly riſes up in a large bubble, which collapſes immediately. A ſmooth ſhilling lying on the bottom will produce this appearance very violently, or a thimble with the mouth down.

11 Water will not boil unleſs the fire be applied to the bottom or ſides of the veſſel.

In order to make water boil, the fire muſt be applied to the bottom or ſides of the veſſel. If the heat be applied at the top of the water, it will waſte away without boiling; for the very ſuperficial particles are firſt ſupplied with the heat neceſſary for rendering them elaſtic, and they fly off without agitating the reſt (A).

Since this diſengagement of vapour is the effect of its

(A) We explained the opaque and cloudy appearance of ſteam, by ſaying that the vapour is condenſed by coming into contact with the cooler air. There is ſomething in the form of this cloud which is very inexplicable. The particles of it are ſometimes very diſtinguiſhable by the eye; but they have not the ſmart ſtar-like brilliancy of very ſmall drops of water, but give the fainter reflection of a very thin film or veſicle like a ſoap bubble. If we attend alſo to their motion, we ſee them deſcending very ſlowly in compariſon with the deſcent of a ſolid drop; and this veſicular conſtitution is eſtabliſhed beyond a doubt by looking at a candle through a cloud of ſteam. It is ſeen ſurrounded by a faint halo with priſmatical colours, preciſely ſuch as we can demonſtrate by optical laws to belong to a collection of veſicles, but totally different from the halo which would be produced by a collection of ſolid drops. It is very difficult to conceive how theſe veſicles can be formed of watery particles, each of which was ſurrounded its elaſticity, and ſince this elaſticity is a determined force when the temperature is given, it follows, that fluids cannot boil till the elaſticity of the vapour overcomes the preſſure of the incumbent fluid and of the atmoſphere. Therefore, when this preſſure is removed or diminiſhed, the fluids muſt ſooner overcome what remains, and boil at a lower temperature. Accordingly it is obſerved that water will boil in an exhauſted receiver when of the heat of the human body. If two glaſs balls A and B (fig. 1.) be connected by a ſlender tube, and one of them A be filled with water (a ſmall opening or pipe *b* being left at top of the other), and this be made to boil, the vapour produced from it will drive all the air out of the other, and will at laſt come out itſelf, producing ſteam at the mouth of the pipe. When the ball B is obſerved to be occupied by tranſparent vapour, we may conclude that the air is completely expelled. Now ſhut the pipe by ſticking it into a piece of tallow or bees-wax; the vapour in B will ſoon condenſe, and there will be a vacuum. The flame of a lamp and blow-pipe being directed to the little pipe, will cauſe it immediately to cloſe and ſeal hermetically. We now have a pretty inſtrument or toy called a PULSE GLASS. Graſp the ball A in the hollow of the hand; the heat of the hand will immediately expand the bubble of vapour which may be in it, and this vapour will drive the water into B, and then will blow up through it for a long while, keeping it in a ſtate of violent ebullition, as long as there remains a drop or film of water in A. But care muſt be taken that B is all the while kept cold, that it may condenſe the vapour as faſt as it riſes through the water. Touching B with the hand, or breathing warm on it, will immediately ſtop the ebullition in it. When the water in A has thus been diſſipated, graſp B in the hand; the water will be driven into A, and the ebullition will take place there as it did in B. Putting one of the balls into the mouth will make the ebullition more violent in the other, and the one in the mouth will feel very cold. This is a pretty illuſtration of the rapid abſorption of the heat by the particles of water which are thus converted into elaſtic vapour. We have ſeen this little toy ſuſpended by the middle of the tube like a balance, and thus placed in the inſide of a window, having two holes *a* and *b* cut in the pane, in ſuch a ſituation that when A is full of water and preponderates, B is oppoſite to the hole *b*. Whenever the room became ſufficiently warm, the vapour was formed in A, and immediately drove the water into B, which was kept cool by the air coming into the room through the hole *b*. By this means B was made to preponderate in its turn, and A was then oppoſite to the hole *a*, and the proceſs was now repeated in the oppoſite direction; and this amuſement continued as long as the room was warm enough.

12
No fluid can boil till the elaſticity of the vapour overcome the preſſure of the incumbent bodies.
Plate DI. Fig. 1.

13
Liquors differ much in the temperature neceſſary for their ebullition.

We know that liquors differ exceedingly in the temperatures neceſſary for their ebullition. This forms the great chemical diſtinction between volatile and fixed bodies. But the difference of temperature in which they boil, or are converted into permanently elaſtic vapour, under the preſſure of the atmoſphere, is not a certain meaſure of their differences of volatility. The natural boiling point of a body is that in which it will be converted into elaſtic vapour under no preſſure, or *in vacuo*. The boiling point in the open air depends on the law of the elaſticity of the vapour in relation to its heat. A fluid A may be leſs volatile, that is, may require more heat to make it boil *in vacuo*, than a fluid B: But if the elaſticity of the vapour of A be more increaſed by an increaſe of temperature than that of the vapour of B, A may boil at as low, or even at a lower temperature, in the open air, than B does; for the increaſed elaſticity of the vapour of A may ſooner overcome the preſſure of the atmoſphere. Few experiments have been made on the relation between the temperature and the elaſticity of different vapours. So long ago as the year 1765, we had occaſion to examine the boiling points of all ſuch liquors as we could manage in an air-pump; that is, ſuch as did not produce vapours which deſtroyed the valves and the leathers of the piſtons: and we thought that the experiments gave us reaſon to conclude, that the elaſticity of all the vapours was affected by heat nearly in the ſame degree. For we found that the difference between their boiling points in the air and *in vacuo* was nearly the ſame in all, namely, about 120 degrees of Fahrenheit's thermometer. It is exceedingly difficult to make experiments of this kind: The vapours are ſo condenſible, and change their elaſticity ſo prodigiouſly by a trifling change of temperature, that it is almoſt impoſſible to examine this point with preciſion. It is, however, as we ſhall ſee by and bye, a ſubject of conſiderable practical importance in the mechanic arts; and an accurate knowledge of the relation would be of great uſe alſo to the diſtiller: and it would be no leſs important to diſcover the relation of their elaſticity and denſity, by examining their compreſſibility, in the ſame manner as we have aſcertained the relation in the caſe of what we call *aerial fluids*, that is, ſuch as we have never obſerved in the form of liquids or ſolids, except in conſequence of their union with each other or with other bodies. In the article PNEUMATICS we took notice of it as ſomething like a natural law, that all theſe airs, or gaſes as they are now called, had their elaſticity very nearly, if not exactly proportional to their denſity. This appears from the experiments of Achard, of Fontana, and others, on vital air, inflammable air, fixed air, and ſome others. It gives us ſome preſumption to ſuppoſe that it holds in all elaſtic vapours whatever, and that it is connected with their elaſticity; and it renders it ſomewhat probable that they are all elaſtic, only becauſe the cauſe of heat (the matter of fire if you will) is elaſtic, and that their law of elaſticity, in reſpect of denſity, is the ſame with that of fire. But it muſt be

14
Difference between their boiling points in air and *in vacuo* about 120°.

rounded with many particles of fire, now communicated to the air, and how each of theſe veſicles ſhall include within it a ball of air; but we cannot refuſe the fact. We know, that if, while linſeed oil is boiling or nearly boiling, the ſurface be obliquely ſtruck with the ladle, it will be daſhed into a prodigious number of exceedingly ſmall veſicles, which will float about in the air for a long while. Mr Sauſſure was (we think) the firſt who diſtinctly obſerved this veſicular form of miſts and clouds; and he makes conſiderable uſe of it in explaining ſeveral phenomena of the atmoſphere.

Steam.

15
To what the elasticity of fluids may be owing.

be obferved, that although we thus affign the elafticity of fire as the immediate caufe of the elafticity of vapour, in the fame way, and on the fame grounds, that we afcribe the fluidity of brine to the fluidity of the water which holds the folid falt in folution, it does not follow that this is owing, as is commonly fuppofed, to a repulfion or tendency to recede from each other exerted by the particles of fire. We are as much entitled to infer a repulfion of unlimited extent between the particles of water; for we fee that by its means a fingle particle of fea-falt becomes diffeminated through the whole of a very large veffel. If water had not been a vifible and palpable fubftance, and the falt only had been vifible and palpable, we might have formed a fimilar notion of chemical folution. But we, on the contrary, have confidered the *quaquaverfum* motion or expanfion of the falt as a diffemination among the particles of water; and we have afcribed it to the ftrong attraction of the atoms of falt for the atoms of water, and the attraction of thefe laft for each other, thinking that each atom of falt accumulates round itfelf a multitude of watery atoms, and by fo doing muft recede from the other faline atoms. Nay, we farther fee, that by forces which we naturally confider as attractions, an expanfion may be produced of the whole mafs, which will act againft external mechanical forces. It is thus that wood fwells with almoft infuperable force by imbibing moifture; it is thus that a fponge immerfed in water becomes really an elaftic compreffible body; refembling a blown bladder; and there are appearances which warrant us to apply this mode of conception to elaftic fluids.—When air is fuddenly compreffed, a thermometer included in it fhows a rife of temperature; that is, an appearance of heat now redundant which was formerly combined. The heat feems to be fqueezed out as the water from the fponge.

16
Afcribed by fome to attraction, but improperly.

Accordingly this opinion, that the elafticity of fteam and other vapours is owing merely to the attraction for fire, and the confequent diffemination of their particles through the whole mafs of fire, has been entertained by many naturalifts, and it has been afcribed entirely to attraction. We by no means pretend to decide; but we think the analogy by far too flight to found any confident opinion on it. The aim is to folve phenomena by attraction only, as if it were of more eafy conception than repulfion. Confidered merely as facts, they are quite on a par. The appearances of nature in which we obferve actual receffes of the parts of body from each other, are as diftinct, and as frequent and familiar, as the appearances of actual reproach. And if we attempt to go farther in our contemplation, and to conceive the way and the forces by which either the approximation or receffes of the atoms are produced, we muft acknowledge that we have no conception of the matter; and we can only fay, that there is a caufe of thefe motions, and we call it a force, as in every cafe of the production of motion. We call it attraction or repulfion juft as we happen to contemplate an accefs or a recefs. But the analogy here is not only flight, but imperfect, and fails moft in thofe cafes which are moft fimple, and where we fhould expect it to be moft complete. We can fqueeze water out of a fponge, it is true, or out of a piece of green wood; but when the white of an egg, the tremella, or fome gums, fwell to a hundred times their dry dimenfions by imbibing water, we cannot fqueeze out a particle. If fluidity (for the reafoning muft equally apply to this as to vapouroufnefs) be owing to an accumulation of the extended matter of fire, which gradually expanded the folid by its very minute additions; and if the accumulation round a particle of ice, which is neceffary for making it a particle of water, be fo great in comparifon of what gives it the expanfion of one degree, as experiment obliges us to conclude—it feems an inevitable confequence that all fluids fhould be many times rarer than the folids from which they are produced. But we know that the difference is trifling in all cafes, and in fome (water, for inftance, and iron) the folid is rarer than the fluid. Many other arguments, (each of them perhaps of little weight when taken alone, but which are all fyftematically connected) concur in rendering it much more probable that the matter of fire, in caufing elafticity, acts immediately by its own elafticity, which we cannot conceive in any other way than as a mutual tendency in its particles to receive from each other; and we doubt not but that, if it could be obtained alone, we fhould find it an elaftic fluid like air. We even think that there are cafes in which it is obferved in this ftate. The elaftic force of gunpowder is very much beyond the elafticity of all the vapours which are produced in its deflagration, each of them being expanded as much as we can reafonably fuppofe by the great heat to which they are expofed. The writer of this article exploded fome gunpowder mixed with a confiderable portion of finely powdered quartz, and another parcel mixed with fine filings of copper. The elafticity was meafured by the penetration of the ball which was difcharged, and was great in the degree now mentioned. The experiment was fo conducted, that much of the quartz and copper was collected; none of the quartz had been melted, and fome of the copper was not melted. The heat, therefore, could not be fuch as to explain the elafticity by expanfion of the vapours; and it became not improbable that fire was acting here as a detached chemical fluid by its own elafticity. But to return to our fubject.

17
More probably owing to a mutual repulfion between the particles of fire.

18
Probably a great difference between condenfible and incondenfible vapours;

There is one circumftance in which we think our own experiments fhow a remarkable difference (at leaft in degree) between the condenfible and incondenfible vapours. It is well known, that when air is very fuddenly expanded, cold is produced, and heat when it is fuddenly condenfed. When making experiments with the hopes of difcovering the connection between the elafticity and denfity of the vapours of boiling water, and alfo of boiling fpirits of turpentine, we found the change of denfity accompanied by a change of temperature vaftly greater than in the cafe of incoercible gafes. When the vapour of boiling water was fuddenly allowed to expand into five times its bulk, we obferved the depreffion of a large and fenfible air thermometer to be at leaft four or five times greater than in a fimilar expanfion of common air of the fame temperature. The chemical reader will readily fee reafons for expecting, on the contrary, a fmaller alteration of temperature, both on account of the much greater rarity of the fluid, and on account of a partial condenfation of its water and the confequent difengagement of combined heat.

19
and alfo fome difference in the chemical conftitution of vapour.

This difference in the quantity of fire which is combined in vapours and gafes is fo confiderable, as to authorize us to fuppofe that there is fome difference in the chemical conftitution of vapours and gafes, and that the connection

Steam.

connection between the specific bases of the vapour and the fire which it contains is not the same in air, for instance, as in the vapour of boiling water; and this difference may be the reason why the one is easily condensible by cold, while the other has never been exhibited in a liquid or solid form, except by means of its chemical union with other substances. In this particular instance we know that there is an essential difference—that in vital or atmospheric air there is not only a prodigious quantity of fire which is not in the vapour of water, but that it also contains light, or the cause of light, in a combined state. This is fully evinced by the great discovery of Mr Cavendish of the composition of water. Here we are taught that water (and consequently its vapour) consists of air from which the light and greatest part of the fire have been separated. And the subsequent discoveries of the celebrated Lavoisier show, that almost all the condensible gases with which we are acquainted consist either of airs which have already lost much of their fire (and perhaps light too), or of matters in which we have no evidence of fire or light being combined in this manner.

This consideration may go far in explaining this difference in the condensibility of these different species of aerial fluids, the gases and the vapours; and it is with this qualification only that we are disposed to allow that all bodies are condensible into liquids or solids by abstracting the heat. In order that vital air may become liquid or solid, we hold that it is not sufficient that a body be presented to it which shall simply abstract its heat. This would only abstract its uncombined fire. But another and much larger portion remains chemically combined by means of light. A chemical affinity must be brought into action which may abstract, not the fire from the oxygen (to speak the language of Mr Lavoisier), but the oxygen from the fire and light. And our production is not the detached basis of air, but detached heat and light, and the formation of an oxide of some kind.

General Observations.

To prosecute the chemical consideration of Steams farther than these general observations, which are applicable to all, would be almost to write a treatise of chemistry, and would be a repetition of many things which have been treated of in sufficient detail in other articles of this work. We shall therefore conclude this article with some other observations, which are also general, with respect to the different kinds of coercible vapours, but which have a particular relation to the following article.

20

Steam rises at different temperatures, according as the air is heavy or light.

Steam or vapour is an elastic fluid, whose elasticity balances the pressure of the atmosphere; and it has been produced from a solid or liquid body raised to a sufficient temperature for giving it this elasticity; that is, for causing the fluid to boil. This temperature must vary with the pressure of the air. Accordingly it is found, that when the air is light (indicated by the barometer being low), the fluid will boil sooner. When the barometer stands at 30 inches, water boils at the temperature 212°. If it stands so low as 28 inches, water will boil at $208\frac{1}{2}$. In the plains of Quito, or at Gondar in Abyssinia, where the barometer stands at about 21 inches, water will boil at 195°. Highly rectified alcohol will boil at 160°, and vitriolic ether will boil at 88° or 89°. This is a temperature by no means uncommon in these places; nay, the air is frequently warmer. Vitriolic ether, therefore, is a liquor which can hardly be known in those countries. It is hardly possible to preserve it in that form. If a phial have not its stopper firmly tied down, it will be blown out, and the liquor will boil and be dissipated in steam. On the top of Chimboraçao, the human blood must be disposed to give out air-bubbles.

21

As fluids under the pressure of the vapour which ascends from them, the conclusion mentioned in no 14. is only a gross approximation.

We said some time ago, that we had concluded, from some experiments made in the receiver of an air-pump, that fluids boil *in vacuo* at a temperature nearly 120 degrees lower than that necessary for their boiling in the open air. But we now see that this must have been but a gross approximation; for in these experiments the fluids were boiling under the pressure of the vapour which they produced, and which could not be abstracted by working the pump. It appears from the experiments of Lord Charles Cavendish, mentioned in the article Pneumatics, that water of the temperature 72° was converted into elastic vapour, which balanced a pressure of $\frac{3}{4}$ths of an inch of mercury, and in this state it occupied the receiver, and did not allow the mercury in the gauge to sink to the level. As fast as this was abstracted by working the air-pump, more of it was produced from the surface of the water, so that the pressure continued the same, and the water did not boil. Had it been possible to produce a vacuum above this water, it would have boiled for a moment, and would even have continued to boil, if the receiver could have been kept very cold.

22

Account of experiments to determine the relation between the temperature of vapour and its elasticity.

Upon reading these experiments, and some very curious ones of Mr Nairne, in the Phil. Transf. vol. lxvii. the writer of this article was induced to examine more particularly the relation between the temperature of the vapour and its elasticity, in the following manner:

Fig. 2.

ABCD (fig. 2.) is the section of a small digester made of copper. Its lid, which is fastened to the body with screws, is pierced with three holes, each of which had a small pipe soldered into it. The first hole was furnished with a brass safety-valve V, nicely fitted to it by grinding. The area of this valve was exactly $\frac{1}{4}$th of an inch. There rested on the stalk at top of this valve the arm of a steelyard carrying a sliding weight. This arm had a scale of equal parts, so adjusted to the weight that the number on the scale corresponded to the inches of mercury, whose pressure on the under surface of the valve is equal to that of the steelyard on its top; so that when the weight was at the division 10, the pressure of the steelyard on the valve was just equal to that of a column of mercury 10 inches high, and $\frac{1}{4}$th of an inch base. The middle hole contained a thermometer T firmly fixed into it, so that no vapour could escape by its sides. The ball of this thermometer was but a little way below the lid. The third hole received occasionally the end of a glass-pipe SGF, whose descending leg was about 36 inches long. When this syphon was not used, the hole was properly shut with a plug.

The vessel was half filled with distilled water which had been purged of air by boiling. The lid was then fixed on, having the third hole S plugged up. A lamp being placed under the vessel, the water boiled, and the steam issued copiously by the safety-valve. The thermometer stood at 213, and a barometer in the room at 29.9 inches. The weight was then put on the fifth division. The thermometer immediately began to rise; and when it was at 220, the steam issued by the sides of

Steam. of the valve. The weight was removed to the 10th divifion; but before the thermometer could be diftinctly obferved, the fteam was iffuing at the valve. The lamp was removed farther from the bottom of the veffel, that the progrefs of heating might be more moderate; and when the fteam ceafed to iffue from the valve, the thermometer was at 227. The weight was now fhifted to 15; and by gradually approaching the lamp, the fteam again iffued, and the thermometer was at $132\frac{1}{2}$. This mode of trial was continued all the way to the 75th divifion of the fcale. The experiments were then repeated in the contrary order; that is, the weight being fufpended at the 75th divifion, and the fteam iffuing ftrongly at the valve, the lamp was withdrawn, and the moment the fteam ceafed to come out, the thermometer was obferved. The fame was done at the 70th, 65th, divifion, &c. Thefe experiments were feveral times repeated both ways; and the means of all the refults for each divifion are expreffed in the following table, where column 1ft expreffes the elafticity of the fteam, being the fum of 29.9, and the divifion of the fteelyard; column 2d expreffes the temperature of the fteam correfponding to this elafticity.

A very different procefs was neceffary for afcertaining the elafticity of the fteam in lower temperatures, and confequently under fmaller preffures than that of the atmofphere. The glafs fyphon SGF was now fixed into its hole in the lid of the digefter. The water was made to boil fmartly for fome time, and the fteam iffued copioufly both at the valve and at the fyphon. The lower end of the fyphon was now immerfed into a broad faucer of mercury, and the lamp inftantly removed, and every thing was allowed to grow cold. By this the fteam was gradually condenfed, and the mercury rofe in the fyphon, without fenfibly finking in the faucer. The valve and all the joints were fmeared with a thick clammy cement, compofed of oil, tallow, and rofin, which effectually prevented all ingrefs of air. The weather was clear and frofty, and the barometer ftanding at 29.84, and the thermometer in the veffel at 42°. The mercury in the fyphon ftood at 29.7, or fomewhat higher, thus fhowing a very complete condenfation. The whole veffel was furrounded with pounded ice, of the temperature 32°. This made no fenfible change in the height of the mercury. A mark was now made at the furface of the mercury. One obferver was ftationed at the thermometer, with inftructions to call out as the thermometer reached the divifions 42, 47, 52, 57, and fo on by every five degrees till it fhould attain the boiling heat. Another obferver noted the correfponding defcents of the mercury by a fcale of inches, which had its beginning placed at 29.84 from the furface of the mercury in the faucer. Steam.

The pounded ice was now removed, and the lamp placed at a confiderable diftance below the veffel, fo as to warm its contents very flowly. Thefe obfervations being very eafily made, were feveral times repeated, and their mean refults are fet down in the following table: Only obferve, that it was found difficult to note down the defcents for every fifth degree, becaufe they fucceeded each other fo faft. Every 10th was judged fufficient for eftablifhing the law of variation. The firft column of the table contains the temperature, and the fecond the defcent (in inches) of the mercury from the mark 29.84.

Four or five numbers at the top of the column of elafticities are not fo accurate as the others, becaufe the mercury paffed pretty quickly through thefe points. But the progrefs was extremely regular through the remaining points; fo that the elafticities correfponding to temperatures above 70° may be confidered as very accurately afcertained.

Not being altogether fatisfied with the method employed for meafuring the elafticity in temperatures above that of boiling water, a better form of experiment was adopted. (Indeed it was the want of other apparatus which made it neceffary to employ the former). A glafs tube was procured of the form reprefented in fig. 3. having a little ciftern L, from the top and bottom of which proceeded the fyphons K and MN. The ciftern contained mercury, and the tube MN was of a flender bore, and was about fix feet two inches long. The end K was firmly fixed in the third hole of the lid, and the long leg of the fyphon was furnifhed with a fcale of inches, and firmly faftened to an upright poft. Fig. 3.

The lamp was now applied at fuch a diftance from the veffel as to warm it flowly, and make the water boil, the fteam efcaping for fome time through the fafety-valve. A heavy weight was then fufpended on the fteelyard; fuch as it was known that the veffel would fupport, and at the fame time, fuch as would not allow the fteam to force the mercury out of the long tube. The thermometer began immediately to rife, as alfo the mercury

Steam.

mercury in the tube MN. Their correfpondent ftations are marked in the following table :

Temperature.	*Elafticity.*
212°	0.0
220	5.9

270	64.2
280	106.0

This form of the experiment is much more fufceptible of accuracy than the other, and the meafures of elafticity are more to be depended on. In repeating the experiment, they were found much more conftant ; whereas, in the former method, differences occurred of two inches and upwards.

We may now connect the two fets of experiments into one table, by adding to the numbers in this laft table the conftant height 29.9, which was the height of the mercury in the barometer during the laft fet of obfervations.

23
Which agree well with thofe of Mr Achard.

In the memoirs of the Royal Academy of Berlin for 1782, there is an account of fome experiments made by Mr Achard on the elaftic force of fteam, from the temperature 32° to 212°. They agree extremely well with thofe mentioned here, rarely differing more than two or three tenths of an inch. He alfo examined the elafticity of the vapour produced from alcohol, and found, that when the elafticity was equal to that of the vapour of water, the temperature was about 35° lower. Thus, when the elafticity of both was meafured by 28.1 inches of mercury, the temperature of the watery vapour was 209°, and that of the fpirituous vapour was 173°. When the elafticity was 18.5, the temperature of the water was 189.5, and that of the alcohol 154.6. When the elafticity was 11.05, the water was 168°, and the alcohol 134°.4. Obferving the difference between the temperatures of equally elaftic vapours of water and alcohol not to be conftant, but gradually to diminifh, in Mr Achard's experiments, along with the elafticity, it became interefting to difcover whether and at what temperature this difference would vanifh altogether. Experiments were accordingly made by the writer of this article, fimilar to thofe made with water. They were not made with the fame fcrupulous care, nor repeated as they deferved, but they furnifhed rather an unexpected refult. The following table will give the reader a diftinct notion of them :

Temperature.	*Elafticity.*
32°	0.0
40	0.1
60	0.8
80	0.8
100	3.9
120	6.9
140	12.2
160	21.3
180	34.
200	52.4
220	78.5
240	115.

24
An unexpected refult in comparing the temperatures of equally elaftic vapours of water and alcohol.

We fay that the refult was unexpected ; for as the natural boiling point feemed by former experiments to be in all fluids about 120° or more below their boiling point in the ordinary preffure of the atmofphere, it was reafonable to expect that the temperature at which they ceafed to emit fenfibly elaftic fteam would have fome relation to their temperatures when emitting fteam of any determinate elafticity. Now as the vapour of alcohol of elafticity 30 has its temperature about 36° lower than the temperature of water equally elaftic, it was to be expected that the temperature at which it ceafed to be fenfibly affected would be feveral degrees lower than 32°. It is evident, however, that this is not the cafe. But this is a point that deferves more attention, becaufe it is clofely connected with the chemical relation between the element (if fuch there be) of fire and the bodies into whofe compofition it feems to enter as a conftituent part. What is the temperature 32°, to make it peculiarly connected with elafticity ? It is a temperature affumed by us for our own conveniency, on account of the familiarity of water in our experiments. Ether, we know, boils in a temperature far below this, as appears from Dr Cullen's experiments narrated in the Effays Phyfical and Literary of Edinburgh. On the faith of former experiments, we may be pretty certain that it will boil in vacuo at the temperature —14°, becaufe in the air it boils at +106°. Therefore we may be certain, that the fteam or vapour of ether, when of the temperature 32°, will be very fenfibly elaftic. Indeed Mr Lavoifier fays, that if it be expofed in an exhaufted receiver in winter, its vapour will fupport mercury at the height of 10 inches. A feries of experiments on this vapour fimilar to the above would be very inftructive. We even wifh that thofe on alcohol were more carefully repeated. If we draw a curve line, of which the abfciffa is the line of temperatures, and the ordinates are the correfponding heights of the mercury in thefe experiments on water and alcohol,

Steam.

we shall obseive, that although they both sensibly coincide at 32°, and have the abscissa for their common tangent, a very small error of observation may be the cause of this, and the curve which expresses the elasticity of spirituous vapour may really intersect the other, and go backwards considerably beyond 32°.

25
These experiments give rise to important reflections.

This range of experiments gives rise to some curious and important reflections. We now see that no particular temperature is necessary for water assuming the form of permanently elastic vapour; and that it is highly probable that it assumes this form even at the temperature 32°; only its elasticity is too small to afford us any sensible measure. It is well known that even ice evaporates (see experiments to this purpose by Mr Wilson in the Philosophical Transactions, when a piece of polished metal covered with hoar-frost became perfectly clear by exposing it to a dry frosty wind). Vol. lxx.

Even mercury evaporates, or is converted into elastic vapour, when all external pressure is removed. The dim film which may frequently be observed in the upper part of a barometer which stands near a stream of air, is found to be small globules of mercury sticking to the inside of the tube. They may be seen by the help of a magnifying glass, and are the best test of a well made barometer. They will be entirely removed by causing the mercury to rise along the tube. It will lick them all up. They consist of mercury which had evaporated in the void space, and was afterwards condensed by the cold glass. But the elasticity is too small to occasion a sensible depression of the column, even when considerably warmed by a candle.

26
Spontaneous evaporation produced by the dissolving power of the air.

Many philosophers accordingly imagine, that spontaneous evaporation in low temperatures is produced in this way. But we cannot be of this opinion, and must still think that this kind of evaporation is produced by the dissolving power of the air. When moist air is suddenly rarefied, there is always a precipitation of water. This is most distinctly seen when we work an air-pump briskly. A mist is produced, which we see plainly fall to the bottom of the receiver. But by this new doctrine the very contrary should happen, because the tendency of water to appear in the elastic form is promoted by removing the external pressure; and we really imagine that more of it now actually becomes simple elastic watery vapour. But the mist or precipitation shows incontrovertibly, that there had been a previous solution. Solution is performed by forces which act in the way of attraction; or, to express it more safely, solutions are accompanied by the mutual approaches of the particles of the menstruum and solved: all such tendencies are *observed* to increase by a diminution of distance. Hence it *must* follow, that air of double density will dissolve more than twice as much water. Therefore when we suddenly rarefy saturated air (even though its heat should not diminish) some water must be let go. What may be its quantity we know not; but it *may be more* than what would now become elastic by this diminution of surrounding pressure; and it is not unlikely but this may have some effect in producing the vesicles which we found so difficult to explain. These may be filled with pure watery vapour, and be floating in a fluid composed of water dissolved in air. An experiment of Fontana's seems to put this matter out of doubt. A distilling apparatus AB (fig. 4.) was so contrived, that the heat was applied above the surface of the water in the alembic A. This was done by inclosing it in another vessel CC, filled with hot water. In the receiver B there was a sort of barometer D, with an open cistern, in order to see what pressure there was on the surface of the fluid. While the receiver and alembic contained air, the heat applied at A produced no sensible distillation during several hours: But on opening a cock E in the receiver at its bottom, and making the water in the alembic to boil, steam was produced which soon expelled all the air, and followed it through the cock. The cock was now shut, and the whole allowed to grow cold by removing the fire, and applying cold water to the alembic. The barometer fell to a level nearly. Then warm water was allowed to get into the outer vessel CC. The barometer rose a little, and the distillation went on briskly without the smallest ebullition in the alembic. The conclusion is obvious: while there was air in the receiver and communicating pipe, the distillation proceeded entirely by the dissolving power of this air. Above the water in the alembic it was quickly saturated; and this saturation proceeded slowly along the still air in the communicating pipe, and at last might take place through the whole of the receiver. The sides of the receiver being kept cold, should condense part of the water dissolved in the air in contact with them, and this should trickle down the sides and be collected. But any person who has observed how long a crystal of blue vitriol will lie at the bottom of a glass of still water before the tinge will reach the surface, will see that it must be next to impossible for distillation to go on in these circumstances; and accordingly none was observed. But when the upper part of the apparatus was filled with pure watery vapour, it was supplied from the alembic as fast as it was condensed in the receiver, just as in the pulse glass.

Fig. 4.

27
A certain law in the dilatation of aeriform fluids by heat.

Another inference which may be drawn from these experiments is, that Nature seems to affect a certain law in the dilatation of aeriform fluids by heat. They seem to be dilatable nearly in proportion of their present dilatation. For if we suppose that the vapours resemble air, in having their elasticity in any given temperature proportional to their density, we must suppose that if steam of the elasticity 60, that is, supporting 60 inches of mercury, were subjected to a pressure of 30 inches, it would expand into twice its present bulk. The augmentation of elasticity therefore is the measure of the bulk into which it would expand in order to acquire its former elasticity. Taking the increase of elasticity therefore as a measure of the bulk into which it would expand under one constant pressure, we see that equal increments of temperature produce nearly equal multiplications of bulk. Thus if a certain diminution of temperature diminishes its bulk $\frac{1}{4}$th, another equal diminution of temperature will diminish this new bulk $\frac{1}{4}$th very nearly. Thus, in our experiments, the temperatures 110°, 140°, 170°, 200°, 230°, are in arithmetical progression, having equal differences; and we see that the corresponding elasticities 2.25, 5.15, 11.05, 22.62, 44.7, are very nearly in the continued proportion of 1 to 2. The elasticity corresponding to the temperature 260 deviates considerably from this law, which would give 88 or 89 instead of 80; and the deviation

Steam.

deviation increafes in the higher temperatures. But ftill we fee that there is a confiderable approximation to this law; and it will frequently affift us to recollect, that whatever be the prefent temperature, an increafe of 30 degrees doubles the elafticity and the bulk of watery vapour.

That 4° will increafe the elafticity from			1 to $1\frac{1}{10}$
8	-	-	1 to $1\frac{1}{5}$
10	-	-	1 to $1\frac{1}{4}$
$12\frac{1}{2}$	-	-	1 to $1\frac{1}{3}$
18	-	-	1 to $1\frac{1}{2}$
22	-	-	1 to $1\frac{2}{3}$
24	-	-	1 to $1\frac{3}{4}$
26	-	-	1 to $1\frac{4}{5}$

This is fufficiently exact for moft practical purpofes. Thus an engineer finds that the injection cools the cylinder of a fteam-engine to 192°. It therefore leaves a fteam whofe elafticity is three-fifths of its full elafticity, = 18 inches ☿. But it is better at all times to have recourfe to the table. Obferve, too, that in the lower temperatures, i. e. below 110°, this increment of temperature does more than double the elafticity.

28
Obtains more remarkably in the incoercible vapours.

This law obtains more remarkably in the incoercible vapours; fuch as vital air, atmofpheric air, fixed air, &c. all of which have alfo their elafticity proportional to their bulk inverfely: and perhaps the deviation from the law in fteams is connected with their chemical difference of conftitution. If the bulk were always augmented in the fame proportion by equal augmentations of temperature, the elafticities would be accurately reprefented by the ordinates of a logarithmic curve, of which the temperatures are the correfponding abfciffæ; and we might contrive fuch a fcale for our thermometer, that the temperatures would be the common logarithms of the elafticities, or of the bulks having equal elafticity; or, with our prefent fcale, we may find fuch a multiplier m for the number x of degrees of our thermometer (above that temperature where the elafticity is equal to unity), that this multiple fhall be the common logarithm of the elafticity y; fo that $mx = \log. y$.

But our experiments are not fufficiently accurate for determining the temperature where the elafticity is meafured by 1 inch; becaufe in thefe temperatures the elafticities vary by exceedingly fmall quantities. But if we take 11.04 for the unit of elafticity, and number our temperature from 170°, and make $m = 0.010035$, we fhall find the product mx to be very nearly the logarithm of the elafticity. The deviations, however, from this law, are too great to make this equation of any ufe. But it is very practicable to frame an equation which fhall correfpond with the experiments to any degree of accuracy; and it has been done for air in a tranflation of General Roy's Meafurement of the Bafe at Hounflow Heath into French by Mr Prony. It is as follows: Let x be the degrees of Reaumur's thermometer; let y be the expanfion of 10.000 parts of air; let e be $= 10$, $m = 2.7979$, $n = 0.01768$: then $y = e^{m+nx} - 627.5$. Now e being $= 10$, it is plain that e^{m+nx} is the number, of which $m+nx$ is the common logarithm. This formula is very exact as far as the temperature 60°: but beyond this it needs a correction; becaufe air, like the vapour of water, does not expand in the exact proportion of its bulk.

29
And is confiderably approximated to in the augmentation of the bulk or elafticity of elaftic vapours.

We obferve this law confiderably approximated to in the augmentation of the bulk or elafticity of elaftic vapours; that is, it is a fact that a given increment of temperature makes very nearly the fame proportional augmentation of bulk and elafticity. This gives us fome notion of the manner in which the fuppofed expanding caufe produces the effect. When vapour of the bulk 4 is expanded into a bulk 5 by an addition of 10 degrees of fenfible heat, a certain quantity of fire goes into it, and is accumulated round each particle, in fuch a manner that the temperature of each, which formerly was m, is now $m+10$. Let it now receive another equal augmentation of temperature. This is now $m+20$, and the bulk is $\frac{5\times 5}{4}$ or $6\frac{1}{4}$, and the arithmetical increafe of bulk is $1\frac{1}{4}$. The abfolute quantity of fire which has entered it is greater than the former, both on account of the greater augmentation of fpace and the greater temperature. Confequently if this vapour be compreffed into the bulk 5, there muft be heat or fire in it which is not neceffary for the temperature $m+20$, far lefs for the temperature $m+10$. It muft therefore emerge, and be difpofed to enter a thermometer which has already the temperature $m+20$: that is, the vapour muft grow hotter by compreffion; not by fqueezing out the heat, like water out of a fponge, but becaufe the law of attraction for heat is deranged. It would be a very valuable acquifition to our knowledge to learn with precifion the quantity of fenfible heat produced in this way; but no fatisfactory experiments have yet been made. M. Lavoifier, with his chemical friends and colleagues, were bufily employed in this inquiry: but the wickednefs of their countrymen deprived the world of this and many other important additions which we might have expected from this celebrated and unfortunate philofopher. He had made, in conjunction with M. de la Place, a numerous train of accurate and expenfive experiments for meafuring the quantity of latent or combined heat in elaftic vapours. This is evidently a very important point to the diftiller and practical chemift. This heat muft all come from the fuel; and it is greatly worth while to know whether any faving may be made of this article. Thus we know that diftillation will go on either under the preffure of the air, or in an alembic and receiver from which the air has been expelled by fteam; and we know that this laft may be conducted in a very low temperature, even not exceeding that of the human body. But it is uncertain whether this may not employ even a greater quantity of fuel, as well as occafion a great expence of time. We are difpofed to think, that when there is no air in the apparatus, and when the condenfation can be fpeedily performed, the proportion of fuel expended to the fluid which comes over will diminifh continually as the heat, and confequently the denfity of the fteam, is augmented; becaufe in this cafe the quantity of combined heat muft be lefs. In the mean time, we earneftly recommend the trial of this mode of diftillation in veffels cleared of air. It is undoubtedly of great advantage to be able to work with fmaller fires; and it would fecure us againft all accidents of blowing off the

Steam. the head of the still, often attended with terrible consequences (B).

We must not conclude this article without taking notice of some natural phenomena which seem to owe their origin to the action of elastic steam.

We have already taken notice of the resemblance of the tremor and succussions observed in the shocks of many earthquakes to those which may be felt in a vessel where water is made to boil internally, while the breaking out of the ebullition is stifled by the cold of the upper parts; and we have likewise stated the objections which are usually made to this theory of earthquakes. We may perhaps resume the subject under the article VOLCANO; but in the mean time we do not hesitate to say, that the wonderful appearances of the Geyzer spring in Iceland (see HUER; and ICELAND, N° 3—5.) are undoubtedly produced by the expansion of steam in ignited caverns. Of these appearances we suppose the whole train to be produced as follows.

30 Explanation of the phenomena of the Geyzer spring in Iceland by the force of steam. Fig. 5.

A cavern may be supposed of a shape analogous to CBDEF (fig. 5.), having a perpendicular funnel AB issuing from a depressed part of the roof. The part F may be lower than the rest, remote, and red-hot. Such places we know to be frequent in Iceland. Water may be continually trickling into the part CD. It will fill it up to B, and even up to E *e*, and then trickle slowly along into F. As soon as any gets into contact with an ignited part, it expands into elastic steam, and is partly condensed by the cold sides of the cavern, which it gradually warms, till it condenses no more. This production of steam hinders not in the smallest degree the trickling of more water into F, and the continual production of more steam. This now presses on the surface of the water in CD, and causes it to rise gradually in the funnel BA; but slowly, because its cold surface is condensing an immense quantity of steam. We may easily suppose that the water trickles faster into F than it is expended in the production of steam; so that it reaches farther into the ignited part, and may even fall in a stream into some deeper pit highly ignited. It will now produce steam in vast abundance, and of prodigious elasticity; and at once push up the water through the funnel in a solid jet, and to a great height. This must continue till the surface of the water sinks to BD. If the lower end of the funnel have any inequalities or notches, as is most likely, the steam will get admission along with the water, which in this particular place is boiling hot, being superficial, and will get to the mouth of the funnel, while water is still pressed in below. At last the steam gets in at B on all sides; and as it is converging to B, along the surface of the water, with prodigious velocity it sweeps along with it much water, and blows it up through the funnel with great force. When this is over, the remaining steam blows out unmixed with water, growing weaker as it is expended, till the bottom of the funnel is again stopped by the water increasing in the cavern CBD. All the phenomena above ground are perfectly conformable to the necessary consequences of this very probable construction of the cavern. The feeling of being lifted up, immediately before the jet, in all probability is owing to a real heaving up of the whole roof of the cavern by the first expansion of the great body of steam. We had an accurate description of the phenomena from persons well qualified to judge of these matters who visited these celebrated springs in 1789.

STEAM-Engine, is the name of a machine which derives its moving power from the elasticity and condensibility of the steam of boiling water. It is the most valuable present which the arts of life have ever received from the philosopher. The mariner's compass, the telescope, gunpowder, and other most useful servants to human weakness and ingenuity, were the productions of chance, and we do not exactly know to whom we are indebted for them; but the steam-engine was, in the very beginning, the result of reflection, and the production of a very ingenious mind; and every improvement it has received, and every alteration in its construction and principles, were also the results of philosophical study.

1 Steam engine invented by the marquis of Worcester.

The steam-engine was beyond all doubt invented by the marquis of Worcester during the reign of Charles II. This nobleman published in 1663 a small book entitled A CENTURY OF INVENTIONS; giving some obscure and enigmatical account of an hundred discoveries or contrivances of his own, which he extols as of great importance to the public. He appears to have been a person of much knowledge and great ingenuity: but his description or accounts of these inventions seem not so much intended to instruct the public, as to raise wonder; and his encomiums on their utility and importance

(B) We earnestly recommend this subject to the consideration of the philosopher. The laws which regulate the formation of elastic vapour, or the general phenomena which it exhibits, give us that link which connects chemistry with mechanical philosophy. Here we see chemical affinities and mechanical forces set in immediate opposition to each other, and the one made the indication, characteristic, and measure of the other. We have not the least doubt that they make but one science, the Science of Universal Mechanics; nor do we despair of seeing the phenomena of solution, precipitation, crystallization, fermentation, nay animal and vegetable secretion and assimilation, successfully investigated, as cases of local motion, and explained by the agency of central forces. Some thing of this kind, and that not inconsiderable, was done when Dr Cullen first showed how the double affinities might be illustrated by the assistance of numbers. Dr Black gave to this hint (for it was little more) that elegant precision which characterizes all his views. Mr Kirwan has greatly promoted this study by his numerous and ingenious examples of its application; and the most valuable passages of the writings of Mr Lavoisier, are those where he traces with logical precision the balancings of force which appear in the chemical phenomena. It is from the similar balancings and consequent measurements, which may be observed and obtained in the present case, that we are to hope for admission into this almost unbounded science of contemplation. We have another link equally interesting and promising, viz. the production of heat by friction. This also highly deserves the consideration of the mathematical philosopher.

Steam-Engine.

ance are to a great degree extravagant, resembling more the puff of an advertising tradesman than the patriotic communications of a gentleman. The marquis of Worcester was indeed a projector, and very importunate and mysterious withal in his applications for public encouragement. His account, however, of the steam-engine, although by no means fit to give us any distinct notions of its structure and operation, is exact as far as it goes, agreeing precisely with what we now know of the subject. It is N° 68. of his inventions. His words are as follow: "This admirable method which I propose of raising water by the force of fire has no bounds if the vessels be strong enough: for I have taken a cannon, and having filled it three-fourths full of water, and shut up its muzzle and touch-hole, and exposed it to the fire for 24 hours, it burst with a great explosion. Having afterwards discovered a method of fortifying vessels internally, and combined them in such a way that they filled and acted alternately, I have made the water spout in an uninterrupted stream 40 feet high; and one vessel of rarefied water raised 40 of cold water. The person who conducted the operation had nothing to do but turn two cocks; so that one vessel of water being consumed, another begins to force, and then to fill itself with cold water, and so on in succession."

2
But first reduced to practice by Captain Savary.

It does not appear that the noble inventor could ever interest the public by these accounts. His character as a projector, and the many failures which persons of this turn of mind daily experience, probably prejudiced people against him, and prevented all attention to his projects. It was not till towards the end of the century, when experimental philosophy was prosecuted all over Europe with uncommon ardour, that these notions again engaged attention. Captain Savary, a person also of great ingenuity and ardent mind, saw the reality and practicability of the marquis of Worcester's project. He knew the great expansive power of steam, and had discovered the inconceivable rapidity with which it is reconverted into water by cold; and he soon contrived a machine for raising water, in which both of these properties were employed. He says, that it was entirely his own invention. Dr Desaguiliers insists that he only copied the marquis's invention, and charges him with gross plagiarism, and with having bought up and burned the copies of the marquis's book, in order to secure the honour of the discovery to himself. This is a very grievous charge, and should have been substantiated by very distinct evidence. Desaguiliers produces none such; and he was much too late to know what happened at that time. The argument which he gives is a very foolish one, and gave him no title to consider Savary's experiment as a falsehood; for it might have happened precisely as Savary relates, and not as it happened to Desaguiliers. The fact is, that Savary obtained his patent of invention after a hearing of objections, among which the discovery of the marquis of Worcester was not mentioned: and it is certain that the account given in the Century of Inventions could instruct no person who was not sufficiently acquainted with the properties of steam to be able to invent the machine himself.

3
Papin has no claim to the invention as the French pretend.

Captain Savary obtained his patent *after having actually erected* several machines, of which he gave a description in a book intitled THE MINER'S FRIEND, published in 1696, and in another work published in 1699. Much about this time Dr Papin, a Frenchman and fellow of the Royal Society, invented a method of dissolving bones and other animal solids in water, by confining them in close vessels, which he called DIGESTERS, so as to acquire a great degree of heat. For it must be observed in this place, that it had been discovered long before (in 1684) by Dr Hooke, the most inquisitive experimental philosopher of that inquisitive age, that water could not be made to acquire above a certain temperature in the open air; and that as soon as it begins to boil, its temperature remains fixed, and an increase of heat only produces a more violent ebullition, and a more rapid waste. But Papin's experiments made the elastic power of steam very familiar to him: and when he left England and settled as professor of mathematics at Marpurgh, he made many aukward attempts to employ this force in mechanics, and even for raising water. It appears that he had made experiments with this view in 1698, by order of Charles, landgrave of Hesse. For this reason the French affect to consider him as the inventor of the steam-engine. He indeed published some account of his invention in 1707; but he acknowledges that Captain Savary had also, and without any communication with him, invented the same thing. Whoever will take the trouble of looking at the description which he has given of these inventions, which are to be seen in the *Acta Eruditorum Lipsiæ*, and in Leupold's *Theatrum Machinarum*, will see that they are most aukward, absurd, and impracticable. His conceptions of natural operations were always vague and imperfect, and he was neither philosopher nor mechanician.

We are thus anxious about the claim of those gentlemen, because a most respectable French author, Mr Bossut, says in his *Hydrodynamique*, that the first notion of the steam-engine was *certainly* owing to Dr Papin, who had not only invented the digester, but had in 1695 published a little performance describing a machine for raising water, in which the pistons are moved by the vapour of boiling water alternately dilated and condensed. Now the fact is, that Papin's first publication was in 1707, and his piston is nothing more than a floater on the surface of the water, to prevent the waste of steam by condensation; and the return of the piston is not produced, as in the steam-engine, by the condensation of the steam, but by admitting the air and a column of water to press it back into its place. The whole contrivance is so aukward, and so unlike any distinct notions of the subject, that it cannot do credit to any person. We may add, that much about the same time Mr Amontons contrived a very ingenious but intricate machine, which he called a *fire-wheel*. It consisted of a number of buckets placed in the circumference of a wheel, and communicating with each other by very intricate circuitous passages. One part of this circumference was exposed to the heat of a furnace, and another to a stream or cistern of cold water. The communications were so disposed, that the steam produced in the buckets on one side of the wheel drove the water into buckets on the other side, so that one side of the wheel was always much heavier than the other; and it must therefore turn round, and may execute some work. The death of the inventor, and the intricacy of the machine, caused it to be neglected. Another member of the Parisian academy of sciences (Mr Deslandes) also presented to the academy a project of a steam-wheel, where the impulsive force of the vapour

4
Mr Amontons's fire-wheel.

pour was employed; but it met with no encouragement. The English engineers had by this time so much improved Savary's first invention, that it supplanted all others. We have therefore no hesitation in giving the honour of the first and complete invention to the marquis of Worcester; and we are not disposed to refuse Captain Savary's claim to originality as to the construction of the machine, and even think it probable that his own experiments made him see the whole, independent of the marquis's account.

Captain Savary's engine, as improved and simplified by himself, is as follows.

5
Captain Savary's steam-engine described.

Fig. 6.

A (fig. 6.) represents a strong copper boiler properly built up in a furnace. There proceeds from its top a large steam-pipe B, which enters into the top of another strong vessel R called the RECEIVER. This pipe has a cock at C called the STEAM-COCK. In the bottom of the receiver is a pipe F, which communicates sidewise with the rising pipe KGH. The lower end H of this pipe is immersed in the water of the pit or well, and its upper part K opens into the cistern into which the water is to be delivered. Immediately below the pipe of communication F there is a valve G, opening when pressed from below, and shutting when pressed downwards. A similar valve is placed at I, immediately above the pipe of communication. Lastly, there is a pipe ED which branches off from the rising pipe, and enters into the top of the receiver. This pipe has a cock D called the INJECTION-COCK. The mouth of the pipe ED has a nozzle f pierced with small holes, pointing from a centre in every direction. The keys of the two cocks C and D are united, and the handle $g\,h$ is called the REGULATOR.

Let the regulator be so placed that the steam-cock C is open and the injection-cock D is shut; put water into the boiler A, and make it boil strongly. The steam coming from it will enter the receiver, and gradually warm it, much steam being condensed in producing this effect. When it has been warmed so as to condense no more, the steam proceeds into the rising pipe; the valve G remains shut by its weight; the steam lifts the valve I, and gets into the rising pipe, and gradually warms it. When the workman feels this to be the case, or hears the rattling of the valve I, he immediately turns the steam-cock so as to shut it, the injection-cock still remaining shut (at least we may suppose this for the present.) The apparatus must now cool, and the steam in the receiver collapses into water. There is nothing now to balance the pressure of the atmosphere; the valve I remains shut by its weight; but the air incumbent on the water in the pit presses up this water through the suction-pipe HG, and causes it to lift the valve G, and flow into the receiver R, and fill it to the top, if not more than 20 or 25 feet above the surface of the pit water.

The steam-cock is now opened. The steam which, during the cooling of the receiver, has been accumulating in the boiler, and acquiring a great elasticity by the action of the fire, now rushes in with great violence, and, pressing on the surface of the water in the receiver, causes it to shut the valve G and open the valve I by its weight alone, and it now flows into the rising pipe, and would stand on a level if the elasticity of the steam were no more than what would balance the atmospherical pressure. But it is much more than this, and therefore it *presses* the water out of the receiver into the rising pipe, and will even cause it to come out at K, if the elasticity of the steam is sufficiently great. In order to ensure this, the boiler has another pipe in its top, covered with a *safety*-valve V, which is kept down by a weight W suspended on a steelyard LM. This weight is so adjusted that its pressure on the safety-valve is somewhat greater than the pressure of a column of water Vk as high as the point of discharge K. The fire is so regulated that the steam is always issuing a little by the loaded valve V. The workman keeps the steam-valve open till he hears the valve I rattle. This tells him that the water is all forced out of the receiver, and that the steam is now following it. He immediately turns the regulator which shuts the steam-cock, and now, for the first time, opens the injection-cock. The cold water trickles at first through the holes of the nozzle f, and falling down through the steam, begins to condense it; and then its elasticity being less than the pressure of the water in the pipe KEDf, the cold water spouts in all directions through the nozzle, and, quick as thought, produces a complete condensation. The valve G now opens again by the pressure of the atmosphere on the water of the pit, and the receiver is soon filled with cold water. The injection-cock is now shut, and the steam-cock opened, and the whole operation is now repeated; and so on continually.

This is the simple account of the process, and will serve to give the reader an introductory notion of the operation; but a more minute attention must be paid to many particulars before we can see the properties and defects of this ingenious machine.

6
Defects of this machine such,

The water is driven along the rising pipe by the elasticity of the steam. This must in the boiler, and every part of the machine, exert a pressure on every square inch of the vessels equal to that of the upright column of water. Suppose the water to be raised 100 feet, about 25 of this may be done in the suction-pipe; that is, the upper part of the receiver may be about 25 feet above the surface of the pit-water. The remaining 75 must be done by forcing, and every square inch of the boiler will be squeezed out by a pressure of more than 30 pounds. This very moderate height therefore requires very strong vessels; and the marquis of Worcester was well aware of the danger of their bursting. A copper boiler of six feet diameter must be nine-tenths of an inch thick to be just in equilibrio with this pressure: and the soldered joint will not be able to withstand it, especially in the high temperature to which the water must be heated in order to produce steam of sufficient elasticity. By consulting the table of the elasticity of steam deduced from our experiments mentioned in the preceding article, we see that this temperature must be at least 280° of Fahrenheit's thermometer. In this heat soft solder is just ready to melt, and has no tenacity; even spelter solder is considerably weakened by it. Accordingly, in a machine erected by Dr Desaguiliers, the workman having loaded the safety-valve a little more than usual to make the engine work more briskly, the boiler burst with a dreadful explosion, and blew up the furnace and adjoining parts of the building as if it had been gunpowder. Mr Savary succeeded pretty well in raising moderate quantities of water to small heights, but could make nothing of deep mines. Many attempts were made, on the marquis's

Steam-Engine.

quis's principle, to ſtrengthen the veſſels from within by radiated bars and by hoops, but in vain. Very ſmall boilers or evaporators were then tried, kept red hot, or nearly ſo, and ſupplied with a ſlender ſtream of water trickling into them; but this afforded no opportunity of making a collection of ſteam during the refrigeration of the receiver, ſo as to have a magazine of ſteam in readineſs for the next forcing operation; and the working of ſuch machines was always an employment of great danger and anxiety.

7
That it can be employed with advantage only in certain ſituations.

The only ſituation in which this machine could be employed with perfect ſafety, and with ſome effect, was where the whole lift did not exceed 30 or 35 feet. In this caſe the greateſt part of it was performed by the ſuction-pipe, and a very manageable preſſure was ſufficient for the reſt. Several machines of this kind were erected in England about the beginning of this century. A very large one was erected at a ſalt-work in the ſouth of France. Here the water was to be raiſed no more than 18 feet. The receiver was capacious, and it was occaſionally ſupplied with ſteam from a ſmall ſalt-pan conſtructed on purpoſe with a cover. The entry of the ſteam into the receiver merely allowed the water to run out of it by a large valve, which was opened by the hand, and the condenſation was produced by the help of a ſmall forcing pump alſo worked by the hand. In ſo particular a ſituation as this (and many ſuch may occur in the endleſs variety of human wants), this is a very powerful engine; and having few moving and rubbing parts, it muſt be of great durability. This circumſtance has occaſioned much attention to be given to this firſt form of the engine, even long after it was ſupplanted by thoſe of a much better conſtruction. A very ingenious attempt was made very lately to adapt this conſtruction to the uſes of the miners. The whole depth of the pit was divided into lifts of 15 feet, in the ſame manner as is frequently done in pump-machines. In each of theſe was a ſuction-pipe 14 feet long, having above it a ſmall receiver like R, about a foot high, and its capacity ſomewhat greater than that of the pipe. This receiver had a valve at the head of the ſuction-pipe, and another opening outwards into the little ciſtern, into which the next ſuction-pipe above dipped to take in water. Each of theſe receivers ſent up a pipe from its top, which all met in the cover of a large veſſel above ground, which was of double the capacity of all the receivers and pipes. This veſſel was cloſe on all ſides. Another veſſel of equal capacity was placed immediately above it, with a pipe from its bottom paſſing through the cover of the lower veſſel and reaching near to its bottom. This upper veſſel communicates with the boiler, and conſtitutes the receiver of the ſteam-engine. The operation is as follows: The lower veſſel is full of water. Steam is admitted into the upper veſſel, which expels the air by a valve, and fills the veſſel. It is then condenſed by cold water. The preſſure of the atmoſphere would cauſe it to enter by all the ſuction-pipes of the different lifts, and preſs on the ſurface of the water in the lower receiver, and force it into the upper one. But becauſe each ſuction-pipe dips in a ciſtern of water, the air preſſes this water before it, raiſes it into each of the little receivers which it fills, and allows the ſpring of the air (which was formerly in them, but which now paſſes up into the lower receiver) to force the water out of the lower receiver into the upper one. When this has been completed, the ſteam is again admitted into the upper receiver. This allows the water to run back into the lower receiver, and the air returns into the ſmall receivers in the pit, and allows the water to run out of each into its proper ciſtern. By this means the water of each pipe has been raiſed 15 feet. The operation may thus be repeated continually.

The contrivance is ingenious, and ſimilar to thoſe which are to be met with in the hydraulics of Schottus, Sturmius, and other German writers. But the operation muſt be exceedingly ſlow; and we imagine that the expence of ſteam muſt be great, becauſe it muſt fill a very large and very cold veſſel, which muſt waſte a great portion of it by condenſation. We ſee by ſome late publications of the very ingenious Mr Blackey, that he is ſtill attempting to maintain the reputation of this machine by ſome contrivances of this kind; but we imagine that they will be ineffectual, except in ſome very particular ſituations.

8
Occaſions great waſte of ſteam and fuel.

For the great defect of the machine, even when we can ſecure it againſt all riſk of burſting, is the prodigious waſte of ſteam, and conſequently of fuel. Daily experience ſhows, that a few ſcattered drops of cold water are ſufficient for producing an almoſt inſtantaneous condenſation of a great quantity of ſteam. Therefore when the ſteam is admitted into the receiver of Savary's engine, and comes into contact with the cold top and cold water, it is condenſed with great rapidity; and the water does not *begin* to ſubſide till its ſurface has become ſo hot that it condenſes no more ſteam. It may now begin to yield to the preſſure of the incumbent ſteam; but as ſoon as it deſcends a little, more of the cold ſurface of the receiver comes into contact with the ſteam, and condenſes more of it, and the water can deſcend no farther till this addition of cold ſurface is heated up to the ſtate of evaporation. This rapid condenſation goes on all the while the water is deſcending. By ſome experiments frequently repeated by the writer of this article, it appears that no leſs than $\frac{11}{12}$ths of the whole ſteam is uſeleſsly condenſed in this manner, and not more than $\frac{1}{12}$th is employed in allowing the water to deſcend by its own weight; and he has reaſon to think that the portion thus waſted will be conſiderably greater, if the ſteam be employed to *force* the water out of the receiver to any conſiderable height.

Obſerve, too, that all this waſte muſt be repeated in every ſucceeding ſtroke; for the whole receiver muſt be cooled again in order to fill itſelf with water.

9
The attempts made to diminiſh this waſte unſucceſsful.

Many attempts have been made to diminiſh this waſte; but all to little purpoſe, becauſe the very filling of the receiver with cold water occaſions its ſides to condenſe a prodigious quantity of ſteam in the ſucceeding ſtroke. Mr Blackey has attempted to leſſen this by uſing two receivers. In the firſt was oil; and into this only the ſteam was admitted. This oil paſſed to and fro between the two receivers, and never touched the water except in a ſmall ſurface. But this hardly produced a ſenſible diminution of the waſte: for it muſt now be obſerved, that there is a neceſſity for the firſt cylinder's being cooled to a conſiderable degree below the boiling point; otherwiſe, though it will condenſe much ſteam, and allow the water to riſe into the receiver, there will be a great diminution of the height of ſuction, unleſs the veſſel be much cooled. This appears plainly by by inſpecting the table of elaſticity. Thus, if the veſſel be cooled no lower than 180°, we ſhould loſe one half of the preſſure of the atmoſphere; if cooled to 120, we ſhould ſtill loſe $\frac{1}{10}$th. The inſpection of this table is of great uſe for underſtanding and improving this noble machine; and without a conſtant recollection of the elaſticity of ſteam correſponding to its actual heat, we ſhall never have a notion of the niceties of its operation.

10 The rapidity with which ſteam is condenſed.

The rapidity with which the ſteam is condenſed is really aſtoniſhing. Experiments have been made on ſteam-veſſels of ſix feet in diameter and ſeven feet high; and it has been found, that about four ounces of water, as warm as the human blood, will produce a complete condenſation in leſs than a ſecond; that is, will produce all the condenſation that it is capable of producing, leaving an elaſticity about one-fifth of the elaſticity of the air. In another experiment with the ſame ſteam-veſſel, no cold water was allowed to get into it, but it was made to communicate by a long pipe four inches in diameter with another veſſel immerſed in cold water. The condenſation was ſo rapid that the time could not be meaſured: it certainly did not exceed half a ſecond. Now this condenſation was performed by a very trifling ſurface of contact, Perhaps we may explain it a little in this way: When a maſs of ſteam, in immediate contact with the cold water, is condenſed, it leaves a void, into which the adjoining ſteam inſtantly expands; and by this very expanſion its capacity for heat is increaſed, or it grows cold, that is, abſtracts the heat from the ſteam ſituated immediately beyond it. And in this expanſion and refrigeration it is itſelf partly condenſed or converted into water, and leaves a void, into which the circumjacent ſteam immediately expands, and produces the ſame effect on the ſteam beyond it. And thus it may happen that the abſtraction of a ſmall quantity of heat from an inconſiderable maſs of ſteam may produce a condenſation which may be very extenſive. Did we know the change made in the capacity of ſteam for heat by a given change of bulk, we ſhould be able to tell exactly what would be the effect of this local actual condenſation. But experiment has not as yet given us any preciſe notions on this ſubject. We think that this rapid condenſation to a great diſtance by a very moderate actual abſtraction of heat is a proof that the capacity of ſteam for heat is prodigiouſly increaſed by expanſion. We ſay a *very moderate actual abſtraction* of heat, becauſe very little heat is neceſſary to raiſe four ounces of blood-warm water to a boiling temperature, which will unfit it for condenſing ſteam. The remarkable phenomenon of ſnow and ice produced in the Hungarian machine, when the air condenſed in the receiver is allowed to blow through the cock (ſee PNEUMATICS), ſhows this to be the caſe in moiſt air, that is, in air holding water in a ſtate of chemical ſolution. We ſee ſomething very like it in a thunder-ſtorm. A ſmall black cloud ſometimes appears in a particular ſpot, and in a very few ſeconds ſpreads over many hundred acres of ſky, that is, a precipitation of water goes on with that rapid diffuſion. We imagine that this increaſe of capacity or demand for heat, and the condenſation that muſt enſue if this demand is not ſupplied, is much more remarkable in pure watery vapours, and that this is a capital diſtinction of their conſtitution from vapours diſſolved in air (A).

The reader muſt now be ſo well acquainted with what paſſes in the ſteam-veſſel, and with the exterior reſults from it, as readily to comprehend the propriety of the changes which we ſhall now deſcribe as having been made in the conſtruction and principle of the ſteam engine. 11

Attempts to improve the ſteam-engine.

Of all places in England the tin-mines of Cornwall ſtood moſt in need of hydraulic aſſiſtance; and Mr Savary was much engaged in projects for draining them by his ſteam-engine. This made its conſtruction and principles well known among the machiniſts and engineers of that neighbourhood. Among theſe were a Mr Newcomen, an ironmonger or blackſmith, and Mr Cawley a glazier at Dartmouth in Devonſhire, who had dabbled much with this machine. Newcomen was a perſon of ſome reading, and was in particular acquainted with the perſon, writings, and projects of his countryman Dr Hooke. There are to be found among Hooke's papers, in the poſſeſſion of the Royal Society, ſome notes of obſervations, for the uſe of Newcomen his countryman, on Papin's boaſted method of tranſmitting to a great diſtance the action of a mill by means of pipes. Papin's project was to employ the mill to work two air-pumps of great diameter. The cylinders of theſe pumps were to communicate by means of pipes with equal cylinders furniſhed with piſtons, in the neighbourhood of a diſtant mine. Theſe piſtons were to be connected, by means of levers, with the piſton-rods of the mine. Therefore, when the piſton of the air-pump at the mill was drawn up by the mill, the correſponding piſton at the ſide of the mine would be preſſed down by the atmoſphere, and thus would raiſe the piſton-rod in the mine, and draw the water. It would appear from theſe notes, that Dr Hooke had diſſuaded Mr Newcomen from erecting a machine on this principle, of which he had expoſed the fallacy in ſeveral diſcourſes before the Royal Society. One paſſage is remarkable. "Could he (meaning Papin) make a ſpeedy vacuum under your ſecond piſton, your work is done."

It is highly probable that, in the courſe of this ſpeculation, it occurred to Mr Newcomen that the vacuum he ſo much wanted might be produced by ſteam, and that this gave riſe to his new principle and conſtruction of the ſteam-engine. The ſpecific deſideratum was in Newcomen's mind; and therefore, when Savary's engine appeared, and became known in his neighbourhood many years after, he would readily catch at the help which it promiſed.

Savary, however, claims the invention as his own; but Switzer, who was perſonally acquainted with both, is poſitive that Newcomen was the inventor. By his principles (as a quaker) being averſe from contention, he was contented to ſhare the honour and the profits with Savary, whoſe acquaintance at court enabled him to procure the patent in 1705, in which all the three were aſſociated. Poſterity has done juſtice to the modeſt inventor, and the machine is univerſally called NEWCOMEN'S

(A) But if it has been found that the condenſation requires more cold water than what is allowed above, and it is ſuſpected that the rapidity of condenſing a large volume of ſteam by the cold ſurface of a veſſel is overrated.

Steam-Engine.

12 Description of Newcomen's. Fig. 7.

MEN's ENGINE. Its principle and mode of operation may be clearly conceived as follows.

Let A (fig. 7.) represent a great boiler properly built in a furnace. At a small height above it is a cylinder CBBC of metal, bored very truly and smoothly. The boiler communicates with this cylinder by means of the throat or steam-pipe NQ. The lower aperture of this pipe is shut by the plate N, which is ground very flat, so as to apply very accurately to the whole circumference of the orifice. This plate is called the regulator or steam-cock, and it turns horizontally round an axis *b a* which passes through the top of the boiler, and is nicely fitted to the socket, like the key of a cock, by grinding. The upper end of this axis is furnished with a handle *b*T.

A piston P is suspended in this cylinder, and made air-tight by a packing of leather or soft rope, well filled with tallow; and, for greater security, a small quantity of water is kept above the piston. The piston-rod PD is suspended by a chain which is fixed to the upper extremity F of the arched head FD of the great lever or WORKING BEAM HK, which turns on the gudgeon O. There is a similar arched head EG at the other end of the beam. To its upper extremity E is fixed a chain carrying the pump-rod XL, which raises the water from the mine. The load on this end of the beam is made to exceed considerably the weight of the piston P at the other extremity.

At some small height above the top of the cylinder is a cistern W called the INJECTION CISTERN. From this descends the INJECTION PIPE ZSR, which enters the cylinder through its bottom, and terminates in a small hole R, or sometimes in a nozzle pierced with many smaller holes diverging from a centre in all directions. This pipe has at S a cock called the INJECTION COCK, fitted with a handle V.

At the opposite side of the cylinder, a little above its bottom, there is a lateral pipe, turning upwards at the extremity, and there covered by a clack-valve *f*, called the SNIFTING VALVE, which has a little dish round it to hold water for keeping it air-tight.

There proceeds also from the bottom of the cylinder a pipe *d e g h* (passing behind the boiler), of which the lower end is turned upwards, and is covered with a valve *h*. This part is immersed in a cistern of water Y, called the HOT WELL, and the pipe itself is called the EDUCTION PIPE. Lastly, the boiler is furnished with a safety-valve called the PUPPET CLACK (which is not represented in this sketch for want of room), in the same manner as Savary's engine. This valve is generally loaded with one or two pounds on the square inch, so that it allows the steam to escape when its elasticity is one-tenth greater than that of common air. Thus all risk of bursting the boiler is avoided, and the pressure outwards is very moderate; so also is the heat. For, by inspecting the table of vaporous elasticity, we see that the heat corresponding to 32 inches of elasticity is only about 216° of Fahrenheit's thermometer.

These are all the essential parts of the engine, and are here drawn in the most simple form, till our knowledge of their particular offices shall show the propriety of the peculiar forms which are given to them. Let us now see how the machine is put in motion, and what is the nature of its work.

13 How the machine is put in motion, and the nature of the work.

The water in the boiler being supposed to be in a state of strong ebullition, and the steam issuing by the safety-valve, let us consider the machine in a state of rest, having both the steam-cock and injection-cock shut. The resting position or attitude of the machine must be such as appears in sketch, the pump rods preponderating, and the great piston being drawn up to the top of the cylinder. Now open the steam-cock by turning the handle T of the regulator. The steam from the boiler will immediately rush in, and flying all over the cylinder, will mix with the air. Much of it will be condensed by the cold surface of the cylinder and piston, and the water produced from it will trickle down the sides, and run off by the eduction-pipe. This condensation and waste of steam will continue till the whole cylinder and piston are made as hot as boiling water. When this happens, the steam will begin to open the snifting valve *f*, and issue through the pipe; slowly at first and very cloudy, being mixed with much air. The blast at *f* will grow stronger by degrees, and more transparent, having already carried off the greatest part of the common air which filled the cylinder. We supposed that the water was boiling briskly, so that the steam was issuing by the safety-valve which is in the top of the boiler, and through every crevice. The opening of the steam-cock puts an end to this at once, and it has sometimes happened that the cold cylinder abstracts the steam from the boiler with such astonishing rapidity, that the pressure of the atmosphere has burst up the bottom of the boiler. We may here mention an accident of which we were witnesses, which also shows the the immense rapidity of the condensation. The boiler was in a frail shed at the side of the engine-house; a shoot of snow from the top of the house fell down and broke through the roof of the shed, and was scattered over the head of the boiler, which was of an oblong or oval shape. In an instant the sides of it were squeezed together by the pressure of the atmosphere.

When the manager of the engine perceives that not only the blast at the snifting valve is strong and steady, but that the boiler is now fully supplied with steam of a proper strength, appearing by the renewal of the discharge at the safety-valve, he shuts the steam-cock, and opens the injection-cock S by turning its handle V. The pressure of the column of water in the injection-pipe ZS immediately forces some water through the spout R. This coming in contact with the pure vapour which now fills the cylinder, condenses it, and thus makes a partial void, into which the more distant steam immediately expands, and by expanding collapses (as has been already observed). What remains in the cylinder no longer balances the atmospherical pressure on the surface of the water in the injection cistern, and therefore the water spouts rapidly through the hole R by the joint action of the column ZS, and the unbalanced pressure of the atmosphere; at the same time the snifting-valve *f*, and the eduction-valve *h*, are shut by the unbalanced pressure of the atmosphere. The velocity of the injection water must therefore rapidly increase, and the jet will dash (if single) against the bottom of the piston, and be scattered through the whole capacity of the cylinder. In a very short space of time, therefore, the condensation of the steam becomes universal, and the elasticity of what remains is almost nothing. The whole pressure preffure of the atmofphere is exerted in the upper furface of the pifton, while there is hardly any on its under fide. Therefore, if the load on the outer end E of the working beam is inferior to this preffure, it muft yield to it. The pifton P muft defcend, and the pump pifton L muft afcend, bringing along with it the water of the mine, and the motion muft continue till the great pifton reaches the bottom of the cylinder; for it is not like the motion which would take place in a cylinder of air rarefied to the fame degree. In this laft cafe, the impelling force would be continually diminifhed, becaufe the capacity of the cylinder is diminifhed by the defcent of the pifton, and the air in it is continually becoming more denfe and elaftic. The pifton would ftop at a certain height, where the elafticity of the included air, together with the load at E, would balance the atmofpheric preffure on the pifton. But when the contents of the cylinder are pure vapour, and the continued ftream of injected cold water keeps down its temperature to the fame pitch as at the beginning, the elafticity of the remaining fteam can never increafe by the defcent of the pifton, nor exceed what correfponds to this temperature. The impelling or accelerating force therefore remains the fame, and the defcent of the pifton will be uniformly accelerated, if there is not an increafe of refiftance arifing from the nature of the work performed by the other end of the beam. This circumftance will come under confideration afterwards, and we need not attend to it at prefent. It is enough for our prefent purpofe to fee, that if the cylinder has been completely purged of common air before the fteam-cock was fhut, and if none has entered fince, the pifton will defcend to the very bottom of the cylinder. And this may be frequently obferved in a good fteam-engine, where every part is air-tight. It fometimes happens, by the pit-pump drawing air, or fome part of the communication between the two ftrains giving way, that the pifton comes down with fuch violence as to knock out the bottom of the cylinder with the blow.

14 The pifton does not begin to defcend the moment the injection is made.

The only obfervation which remains to be made on the motion of the pifton in defcending is, that it does not begin at the inftant the injection is made. The pifton was kept at the top by the preponderancy of the outer end of the working beam, and it muft remain there till the difference between the elafticity of the fteam below it and the preffure of the atmofphere exceeds this preponderancy. There muft therefore be a fmall fpace of time between the beginning of the condenfation and the beginning of the motion. This is very fmall, not exceeding the third or the fourth part of a fecond; but it may be very diftinctly obferved by an attentive fpectator. He will fee, that the inftant the injection cock is opened, the cylinder will fenfibly rife upwards a little by the preffure of the air on its bottom. Its whole weight is not nearly equal to this preffure; and inftead of its being neceffary to *fupport* it by a ftrong floor, we muft *keep it down* by ftrong joifts loaded by heavy walls. It is ufual to frame thefe joints into the pofts which carry the axis of the working-beam, and are therefore loaded with the whole ftrain of the machine. This rifing of the cylinder fhows the inftantaneous commencement of the condenfation; and it is not till *after* this has been diftinctly obferved that the pifton is feen to ftart, and begin to defcend.

When the manager fees the pifton as low as he thinks proper, he fhuts the injection-cock, and opens the fteam-cock. The fteam has been accumulating above the water in the boiler during the whole time of the pifton's defcent, and is now rufhing violently through the puppet clack. The moment, therefore, that the fteam-cock is opened, it rufhes violently into the cylinder, having an elafticity greater than that of the air. It therefore immediately blows open the fnifting valve, and allows (at leaft) the water which had come in by the former injection, and what arofe from the condenfed fteam, to defcend by its own weight through the eduction pipe $d\,e\,g\,h$ to open the valve h, and to run out into the hot well. And we muft eafily fee that this water is boiling hot; for while lying in the bottom of the cylinder, it will condenfe fteam till it acquires this temperature, and therefore cannot run down till it condenfes no more. There is ftill a wafte of fteam at its firft admiffion, in order to heat the infide of the cylinder and the injected water to the boiling temperature: but the fpace being fmall, and the whole being already very warm, this is very foon done; and when things are properly conftructed, little more fteam is wanted than what will warm the cylinder; for the eduction pipe receives the injection water even during the defcent of the pifton, and it is therefore removed pretty much out of the way of the fteam.

15 The circumftances that fucceed the defcent of the pifton.

16 Effects of the firft puff of entering fteam

This firft puff of the entering fteam is of great fervice; it drives out of the cylinder the vapour which it finds there. This is feldom pure watery vapour: all water contains a quantity of air in a ftate of chemical union. The union is but feeble, and a boiling heat is fufficient for difengaging the greateft part of it by increafing its elafticity. It may alfo be difengaged by fimply removing the external preffure of the atmofphere. This is clearly feen when we expofe a glafs of water in an exhaufted receiver. Therefore the fmall fpace below the pifton contains watery vapour mixed with all the air which had been difengaged from the water in the boiler by ebullition, and all that was feparated from the injection water by the diminution of external preffures. All this is blown out of the cylinder by the firft puff of fteam. We may obferve in this place, that waters differ exceedingly in the quantity of air which they hold in a ftate of folution. All fpring water contains much of it: and water newly brought up from deep mines contains a great deal more, becaufe the folution was aided in thefe fituations by great preffures. Such waters fparkle when poured into a glafs. It is therefore of great confequence to the good performance of a fteam-engine to ufe water containing little air, both in the boiler and in the injection-ciftern. The water of running brooks is preferable to all others, and the freer it is from any faline impregnation it generally contains lefs air. Such engines as are fo unfortunately fituated that they are obliged to employ the very water which they have brought up from great depths, are found greatly inferior in their performance to others. The air collected below the pifton greatly diminifhes the accelerating force, and the expulfion of fuch a quantity requires a long-continued blaft of the beft fteam at the beginning of every ftroke. It is advifable to keep fuch water in a large fhallow pond for a long while before ufing it.

17 Of great confequence to the good performance of a fteam-engine, that the water employed contain little air.

18 How the pifton rifes.

Let us now confider the ftate of the pifton. It is evident that it will ftart or begin to rife the moment the

the ſteam-cock is opened; for at that inſtant the exceſs of atmoſpherical preſſure, by which it was kept down in oppoſition to the preponderancy of the outer end of the beam, is diminiſhed. The piſton is therefore *dragged* upwards, and it will riſe even although the ſteam which is admitted be not ſo elaſtic as common air. Suppoſe the mercury in the barometer to ſtand at 30 inches, and that the preponderancy at the outer end of the beam is $\frac{1}{9}$th of the preſſure of the air on the piſton, the piſton will not riſe if the elaſticity of the ſteam is not equal to $30-\frac{30}{9}$°, that is, to 26.7 inches nearly; but if it is juſt this quantity, the piſton will riſe as faſt as this ſteam can be ſupplied through the ſteam-pipe, and the velocity of its aſcent depends entirely on the velocity of this ſupply. This obſervation is of great importance; and it does not ſeem to have occurred to the mathematicians, who have paid moſt attention to the mechaniſm of the motion of this engine. In the mean time, we may clearly ſee that the entry of the ſteam depends chiefly on the counter weight at E: for ſuppoſe there was none, ſteam no ſtronger than air would not enter the cylinder at all; and if the ſteam be ſtronger, it will enter only by the exceſs of its ſtrength. Writers on the ſteam-engine (and even ſome of great reputation) familiarly ſpeak of the ſteam giving the piſton a puſh: But this is ſcarcely poſſible. During the riſe of the piſton the ſnifting valve is never obſerved to blow; and we have not heard any well-atteſted accounts of the piſton-chains ever being ſlackened by the upward preſſure of the ſteam, even at the very beginning of the ſtroke. During the riſing of the piſton the ſteam is (according to the common conception and manner of ſpeaking) *ſucked in*, in the ſame way that air is ſucked into a common ſyringe or pump when we draw up the piſton; for in the ſteam-engine the piſton is really drawn up by the counter weight. But it is ſtill more ſucked in, and requires a more copious ſupply, for another reaſon. As the piſton deſcended only in conſequence of the inſide of the cylinder's being ſufficiently cooled to condenſe the ſteam, this cooled ſurface muſt again be preſented to the ſteam during the riſe of the piſton, and muſt condenſe ſteam a ſecond time. The piſton cannot riſe another inch till the part of the cylinder which the piſton has already quitted has been warmed up to the boiling point, and ſteam muſt be expended in this warming. The inner ſurface of the cylinder is not only of the heat of boiling water while the piſton riſes, but is alſo perfectly dry; for the film of water left on it by the aſcending piſton muſt be completely evaporated, otherwiſe it will be condenſing ſteam. That the quantity thus waſted is conſiderable, appears by the experiments of Mr Beighton. He found that five pints of water were boiled off in a minute, and produced 16 ſtrokes of an engine whoſe cylinder contained 113 gallons of 282 inches each; and he thence concluded that ſteam was 2886 times rarer than water. But in no experiment made with ſcrupulous care on the expanſion of boiling water does it appear that the denſity of ſteam exceeds $\frac{1}{10,000}$th of the denſity of water. Deſaguiliers ſays that it is above 14,000 times rarer than water. We have frequently attempted to meaſure the weight of ſteam which filled a very light veſſel, which held 12,600 grains of water, and found it always leſs than one grain; ſo that we have no doubt of its being much more than 10,000 times rarer than water. This being the caſe, we may ſafely ſuppoſe that the number of gallons of ſteam, inſtead of being 16 times 113, were nearly five times as much; and that only $\frac{1}{5}$th was employed in allowing the piſton to riſe, and the remaining $\frac{4}{5}$ths were employed to warm the cylinder. But no diſtinct experiment ſhews ſo great an expanſion of water when converted into ſteam at 212°. Mr Watt never found it under the preſſure of the air more than 1800 times rarer than water.

19 Its aſcent chiefly owing to the weight of the pit piſton-rods.

The moving force during the aſcent of the piſton muſt be conſidered as reſulting chiefly, if not ſolely, from the preponderating weight of the pit piſton-rods. The office of this is to return the ſteam-piſton to the top of the cylinder, where it may again be preſſed down by the air, and make another working ſtroke by raiſing the pump rods. But the counter-weight at E has another ſervice to perform in this uſe of the engine; namely, to return the pump piſtons into their places at the bottom of their reſpective working barrels, in order that they alſo may make a working ſtroke. This requires force independent of the friction and inertia of the moving parts; for each piſton muſt be puſhed down through the water in the barrel, which muſt riſe through the piſton with a velocity whoſe proportion to the velocity of the piſton is the ſame with that of the bulk of the piſton to the bulk of the perforation through which the water riſes through the piſton. It is enough at preſent to mention this in general terms: we ſhall conſider it more particularly afterwards, when we come to calculate the performance of the engine, and to deduce from our acquired knowledge maxims of conſtruction and improvement.

20 The aſcent of the piſton differs greatly from the deſcent.

From this general conſideration of the aſcent of the piſton, we may ſee that the motion differs greatly from the deſcent. It can hardly be ſuppoſed to accelerate, even if the ſteam in the cylinder were in a moment annihilated. For the reſiſtance to the deſcent of the piſton is the ſame with the weight of the column of water, which would cauſe it to flow through the box of the pump piſton with the velocity with which it really riſes through it, and muſt therefore increaſe as the ſquare of that velocity increaſes; that is, as the ſquare of the velocity of the piſton increaſes. Independent of friction, therefore, the velocity of deſcent through the water muſt ſoon become a maximum, and the motion become uniform. We ſhall ſee by and by, that in ſuch a pump as is generally uſed this will happen in leſs than the 10th part of a ſecond. The friction of the pump will diminiſh this velocity a little, and retard the time of its attaining uniformity. But, on the other hand, the ſupply of ſteam which is neceſſary for this motion, being ſuſceptible of no acceleration from its previous motion, and depending entirely on the briſkneſs of the ebullition, an almoſt inſtantaneous ſtop is put to acceleration.

Accordingly, any perſon who obſerves with attention the working of a ſteam-engine, will ſee that the riſe of the piſton and deſcent of the pump-rods is extremely uniform, whereas the working ſtroke is very ſenſibly accelerated. Before quitting this part of the ſubject, and leſt it ſhould afterwards eſcape our recollection, we may obſerve, that the counter-weight is different during the two motions of the pump-rods. While the machine is making a working ſtroke, it is lifting not only the column

21 The counter-weight is different during the two motions of the pump rods.

lumn of water in the pump, but the abfolute weight of the piftons and pifton-rods alfo: but while the pump-rods are defcending, there is a diminution of the counter-weight by the whole weight loft by the immerfion of the rod in water. The wooden rods which are generally ufed, foaked in water, and joined by iron ftraps, are heavier, and but a little heavier, than water, and they are generally about one-third of the bulk of the water in the pumps.

Thefe two motions complete the period of the operation; and the whole may be repeated by fhutting the fteam-cock and opening the injection-cock whenever the pifton has attained the proper height. We have been very minute in our attention to the different circumftances, that the reader may have a diftinct notion of the ftate of the moving forces in every period of the operation. It is by no means fufficient that we know in general that the injection of cold water makes a void which allows the air to prefs down the pifton, and that the readmiffion of the fteam allows the pifton to rife again. This lumping and flovenly way of viewing it has long prevented even the philofopher from feeing the defects of the conftruction, and the methods of removing them.

22 Difference between Savary's and Newcomen's machines.

We now fee the great difference between Savary's and Newcomen's engine in refpect of principle. Savary's was really an engine which raifed water by the force of fteam; but Newcomen's raifes water entirely by the preffure of the atmofphere, and fteam is employed merely as the moft expeditious method of producing a void; into which the atmofpherical preffure may impel the *firft mover* of his machine. The elafticity of the fteam is not the firft mover.

23 Superiority of Newcomen's.

We fee alfo the great fuperiority of this new machine. We have no need of fteam of great and dangerous elafticity; and we operate by means of very moderate heats, and confequently with much fmaller quantities of fuel; and there is no bounds to the power of this machine. How deep foever a mine may be, a cylinder may be employed of fuch dimenfions that the preffure of the air on its pifton may exceed in any degree the weight of the column of water to be raifed. And laftly, this form of the machine renders it applicable to almoft every mechanical purpofe; becaufe a fkilful mechanic can readily find a method of converting the reciprocating motion of the working beam into a motion of any kind which may fuit his purpofe. Savary's engine could hardly admit of fuch an immediate application, and feems almoft reftricted to raifing water.

24 Gradually improved

Inventions improve by degrees. This engine was firft offered to the public in 1705. But many difficulties occurred in the execution, which were removed one by one; and it was not till 1712 that the engine feemed to give confidence in its efficacy. The moft exact and unremitting attention of the manager was required to the precife moment of opening and fhutting the cocks; and neglect might frequently be ruinous, by beating out the bottom of the cylinder, or allowing the pifton to be wholly drawn out of it. Stops were contrived to prevent both of thefe accidents; then ftrings were ufed to connect the handles of the cocks with the beam, fo that they fhould be turned whenever it was in

25 and fimplified.

certain pofitions. Thefe were gradually changed and improved into detents and catches of different fhapes; at laft, in 1717, Mr Beighton, a very ingenious and well-informed artift, fimplified the whole of thefe fubordinate movements, and brought the machine into the form in which it has continued, without the fmalleft material change, to the prefent day. We fhall now defcribe one of thefe improved engines, copying almoft exactly the drawings and defcription given by Boffut in his *Hydrodynamique*; thefe being by far the moft accurate and perfpicuous of any that have been publifhed.

26 Defcription of Beighton's fteam-engine. Plate DII. Fig. 8.

Fig. 8. N° 1. is a perfpective view of the boiler cylinder, and all the parts neceffary for turning the cocks. Fig. 8. N° 2. is a vertical fection of the fame; and the fame pieces of both are marked with the fame letters of reference.

The rod X of the pifton P is fufpended from the arch of the working beam, as was reprefented in the preceding fketch (fig. 7.). An upright bar of timber FG is alfo feen hanging by a chain. This is fufpended from a concentric arch of the beam, as may be feen alfo in the fketch at $\varphi\ \delta$. The bar is called the *plug-beam*; and it muft rife and fall with the pifton, but with a flower motion. The ufe of this plug-beam is to give motion to the different pieces which turn the cocks.

The fteam-pipe K is of one piece with the bottom of the cylinder, and rifes within it an inch or two, to prevent any of the cold injection water from falling into the boiler. The lower extremity Z of the fteam-pipe penetrates the head of the boiler, projecting a little way. A flat plate of brafs, in fhape refembling a racket or battledore, called the *regulator*, applies itfelf exactly to the whole circumference of the fteam-pipe, and completely excludes the fteam from the cylinder. Being moveable round an upright axis, which is reprefented by the dotted lines at the fide of the fteam-pipe in the profile, it may be turned afide by the handle *i*, n° 1. The profile fhows in the fection of this plate a protuberance in the middle. This refts on a ftrong flat fpring, which is fixed below it athwart the mouth of the fteam-pipe. This fpring preffes it ftrongly towards the fteam-pipe, caufing it to apply very clofe; and this knob flides along the fpring, while the regulator turns to the right or left.

We have faid that the injection-water is furnifhed from a ciftern placed above the cylinder. When the ciftern cannot be fupplied by pipes from fome more elevated fource, its water is raifed by the machine itfelf. A fmall lifting pump *i k* (fig. 7.), called the *jack-head* or *jaquette*, is worked by a rod $\gamma\ \iota$, fufpended from a concentric arch $\iota\ \gamma$ near the outer end of the working beam. This forces a fmall portion of the pit water along the rifing pipe *i* LM into the injection ciftern.

In figure 8. N° 1. and 2. the letters QM 3′ reprefent the pipe which brings down the water from the injection ciftern. This pipe has a cock at R to open or fhut the paffage of this water. It fpouts through the jet 3′, and dafhing againft the bottom of the pifton, it is difperfed into drops, and fcattered through the whole capacity of the cylinder, fo as to produce a rapid condenfation of the fteam.

An upright poft A may be obferved in the perfpective view of the cylinder, &c. This fupports one end B of a horizontal iron axis BC. The end C is fupported by a fimilar poft, of which the place only is marked by the dotted lines A, that the pieces connected

Steam-Engine.

ted with this axis may not be hid by it. A kind of ſtirrup *a b c d* hangs from this axis, ſupported by the hooks *a* and *d*. This ſtirrup is croſſed near the bottom by a round bolt or bar *e*, which paſſes through the eyes or rings that are at the ends of the horizontal fork *h f g*, whoſe long tail *h* is double, receiving between its branches the handle *i* of the regulator. It is plain from this conſtruction, that when the ſtirrup is made to vibrate round the horizontal axis BC, on which it hangs freely by its hooks, the bolt *e* muſt pull or puſh the long fork *h f g* backwards and forwards horizontally, and by ſo doing will move the regulator round its axis by means of the handle *i*. Both the tail of the fork and the handle of the regulator are pierced with ſeveral holes, and a pin is put through them which unites them by a joint. The motion of the handle may be increaſed or diminiſhed by chooſing for the joint a hole near to the axis or remote from it; and the exact poſition at which the regulator is to ſtop on both ſides is determined by pins ſtuck in the horizontal bar on which the end of the handle appears to reſt.

This alternate motion of the regulator to the right and left is produced as follows: There is fixed to the axis BC a piece of iron *o k l*, called the Y, on account of its reſemblance to that letter of the alphabet inverted. The ſtalk *o* carries a heavy lump *p* of lead or iron; and a long leather ſtrap *q p r* is faſtened to *p* by the middle, and the two ends are faſtened to the beam above it, in ſuch a manner that the lump may be alternately catched and held up to the right and left of the perpendicular. By adjuſting the length of the two parts of the ſtrap, the Y may be ſtopped in any deſired poſition. The two claws *k* and *l* ſpread out from each other, and from the line of the ſtalk, and they are of ſuch length as to reach the horizontal bolt *e*, which croſſes the ſtirrup below, but not to reach the bottom of the fork *h f g*. Now ſuppoſe the ſtirrup hanging perpendicularly, and the ſtalk of the Y alſo held perpendicular; carry it a little outward from the cylinder, and then let it go. It will tumble farther out by its weight, without affecting the ſtirrup till the claw *l* ſtrikes on the horizontal bolt *e*, and then it puſhes the ſtirrup and the fork towards the cylinder, and opens the regulator. It ſets it in motion with a ſmart jerk, which is an effectual way of overcoming the coheſion and friction of the regulator with the mouth of the ſteam-pipe. This puſh is adjuſted to a proper length by the ſtrap *q p*, which ſtops the Y when it has gone far enough. If we now take hold of the ſtalk of the Y, and move it up to the perpendicular, the width between its claws is ſuch as to permit this motion, and ſomething more, without affecting the ſtirrup. But when puſhed ſtill nearer to the cylinder, it tumbles towards it by its own weight, and then the claw *k* ſtrikes the bolt *e*, and drives the ſtirrup and fork in the oppoſite direction, till the lump *p* is catched by the ſtrap *rp*, now ſtretched to its full length, while *qp* hangs ſlack. Thus by the motion of the Y the regulator is opened and ſhut. Let us now ſee how the motion of the Y is produced by the machine itſelf. To the horizontal axis BC are attached two ſpanners or handles *m* and *n*. The ſpanner *m* paſſes through a long ſlit in the plug-beam, and is at liberty to move upwards or downwards by its motion round the axis BC. A pin *π* which goes through the plug-beam catches hold of *m* when the beam riſes along with the piſton; and the pin is ſo placed, that when the beam is within an inch or two of its higheſt riſe, the pin has lifted *m* and thrown the ſtalk of the Y paſt the perpendicular. It therefore tumbles over with great force, and gives a ſmart blow to the fork, and immediately ſhuts the regulator. By this motion the ſpanner *m* is removed out of the neighbourhood of the plug-beam. But the ſpanner *n*, moving along with it in the ſame direction, now comes into the way of the pins of the plug-beam. Therefore, when the piſton deſcends again by the condenſation of the ſteam in the cylinder, a pin marked *&* in the ſide of the plug-beam catches hold of the tail of the ſpanner *n*, and by preſſing it down raiſes the lump on the ſtalk of the Y till it paſſes the perpendicular, and it then falls down, outwards from the cylinder, and the claw *l* again drives the fork in the direction *h i*, and opens the ſteam valve. This opening and ſhutting of the ſteam valve is executed in the preciſe moment that is proper, by placing the pins *π* and *&* at a proper height of the plug-beam. For this reaſon, it is pierced through with a great number of holes, that the places of theſe pins may be varied at pleaſure. This, and a proper curvature of the ſpinners *m* and *n*, make the adjuſtment as nice as we pleaſe.

The injection cock R is managed in a ſimilar manner. On its key may be obſerved a forked arm *s t*, like a crab's claw; at a little diſtance above it is the gudgeon or axis *u* of a piece *y u z*, called the hammer or the F, from its reſemblance to that letter. It has a lump of metal *y* at one end, and a ſpear *u s* projects from its middle, and paſſes between the claws *s* and *t* of the arm of the injection-cock. The hammer *y* is held up by a notch in the under ſide of a wooden lever DE, moveable round the center D, and ſupported at a proper height by a ſtring *r* E, made faſt to the joiſt above it.

Suppoſe the injection-cock ſhut, and the hammer in the poſition repreſented in the figure. A pin *β* of the plug-frame riſes along with the piſton, and catching hold of the detent DE, raiſes it, and diſengages the hammer *y* from its notch. This immediately falls down, and ſtrikes a board L put in the way to ſtop it. The ſpear *u s* takes hold of the claw *t*, and forces it aſide towards *x*, and opens the injection-cock. The piſton immediately deſcends, and along with it the plug-frame. During its deſcent the pin *β* meets with the tail *u z* of the hammer, which is now raiſed conſiderably above the level, and brings it down along with it, raiſing the lump *y*, and gradually ſhutting the injection-cock, becauſe the ſpear takes hold of the claw *s* of its arm. When the beam has come to its loweſt ſituation, the hammer is again engaged in the notch of the detent DE, and ſupported by it till the piſton again reaches the top of the cylinder.

In this manner the motions of the injection cock are alſo adjuſted to the preciſe moment that is proper for them. The different pins are ſo placed in the plug-frame, that the ſteam-cock may be completely ſhut before the injection-cock is opened. The inherent motion of the machine will give a ſmall addition to the aſcent of the piſton without expending ſteam all the while; and by leaving the ſteam rather leſs elaſtic than before, the ſubſequent deſcent of the piſton is promoted. There was a conſiderable propriety in the gradual ſhut-

Steam-Engine.

ting of the injection-cock. For after the first dash of the cold water against the bottom of the piston, the condensation is nearly complete, and very little more water is needed; but a continual accession of some is absolutely necessary for completing the condensation, as the capacity of the cylinder diminishes, and the water warms which is already injected.

In this manner the motion of the machine will be repeated as long as there is a supply of steam from the boiler, and of water from the injection cistern, and a discharge procured for what has been injected. We proceed to consider how far these conditions also are provided by the machine itself.

The injection cistern is supplied with water by the jackhead pump, as we have already observed. From this source all the parts of the machine receive their respective supplies. In the first place, a small branch 13, 13, is taken off from the injection-pipe immediately below the cistern, and conducted to the top of the cylinder, where it is furnished with a cock. The spout is so adjusted, that no more runs from it than what will keep a constant supply of a foot of water above the piston to keep it tight. Every time the piston comes to the top of the cylinder, it brings this water along with it, and the surplus of its evaporation and leakage runs off by a waste-pipe 14, 14. This water necessarily becomes almost boiling hot, and it was thought proper to employ its overplus for supplying the waste of the boiler. This was accordingly practised for some time. But Mr Beighton improved this economical thought, by supplying the boiler from the eduction-pipe, 2, 2, the water of which must be still hotter than that above the piston. This contrivance required attention to many circumstances, which the reader will understand by considering the perspective and profile. The eduction-pipe comes out of the bottom of the cylinder at 1 with a perpendicular part, which bends sidewise below, and is shut at the extremity 1. A deep cup 5 communicates with it, holding a metal valve nicely fitted to it by grinding, like the key of a cock. To secure its being always air-tight, a slender stream of water trickles into it from a branch 6 of the waste-pipe from the top of the cylinder. The eduction pipe branches off at 2, and goes down to the hot well, where it turns up, and is covered with a valve. In the perspective view may be observed an upright pipe 4, 4, which goes through the head of the boiler, and reaches to within a few inches of its bottom. This pipe is called the *feeder*, and rises about three or four feet above the boiler. It is open at both ends, and has a branch 3, 3, communicating with the bottom of the cup 5, immediately above the metal valve, and also a few inches below the level of the entry 2 of the eduction-pipe. This communicating branch has a cock by which its passage may be diminished at pleasure. Now suppose the steam in the boiler to be very strong, it will cause the boiling water to rise in the feeding pipe above 3, and coming along this branch, to rise also in the cup 5, and run over. But the height of this cup above the surface of the water in the boiler is such, that the steam is never strong enough to produce this effect. Therefore, on the contrary, any water that may be in the cup 5 will run off by the branch 3, 3, and go down into the boiler by the feeding pipe.

These things being understood, let us suppose a quantity of injected water lying at the bottom of the cylinder. It will run into the eduction-pipe, fill the crooked branch 1, 1, and open the valve in the bottom of the cup (its weight being supported by a wire hanging from a slender spring), and it will fill the cup to the level of the entry 2 of the eduction-pipe, and will then flow along 3, 3, and supply the boiler by the feeder 4, 4. What more water runs in at 1 will now go along the eduction pipe 2, 2, to the hot well. By properly adjusting the cock on the branch 3, 3, the boiler may be supplied as fast as the waste in steam requires. This is a most ingenious contrivance, and does great honour to Mr Beighton. It is not, however, of much importance. The small quantity which the boiler requires may be immediately taken even from a cold cistern, without sensibly diminishing the production of steam: for the quantity of heat necessary for raising the sensible heat of cold water to the boiling temperature is small, when compared with the quantity of heat which must then be combined with it in order to convert the water into steam. For the heat expended in boiling off a cubic foot of water is about six times as much as would bring it to a boiling heat from the temperature of 55°. No difference can be observed in the performance of such engines, and of those which have their boilers supplied from a brook. It has, however, the advantage of being purged of air; and when an engine must derive all its supplies from pit water, the water from the eduction-pipe is vastly preferable to that from the top of the cylinder.

27 An ingenious contrivance.

We may here observe, that many writers (among them the Abbé Bossut), in their descriptions of the steam-engine, have drawn the branch of communication 3, 3, from the feeding-pipe to a part of the crooked pipe 1, 1, lying below the valve in the cup 5. But this is quite erroneous; for, in this case, when the injection is made into the cylinder, and a vacuum produced, the water from the boiler would immediately rush up through the pipes 4, 3, and spout up into the cylinder: so would the external air coming in at the top of the feeder.

28 Which enables us to form some judgement of the internal state of the engine during the performance.

This contrivance has also enabled us to form some judgement of the internal state of the engine during the performance. Mr Beighton paid a minute attention to the situation of the water in the feeders and eduction-pipe of an engine, which seems to have been one of the best which has yet been erected. It was lifting a column of water whose weight was four-sevenths of the pressure of the air on its piston, and made 16 strokes, of six feet each, in a minute. This is acknowledged by all to be a very great performance of an engine of this form. He concluded that the elasticity of the steam in the cylinder was never more than one-tenth greater or less than the elasticity of the air. The water in the feeder never rose more than three feet and a half above the surface of the boiling water, even though it was now lighter by $\frac{1}{27}$th than cold water. The eduction-pipe was only four feet and a half long (vertically), and yet it always discharged the injection water completely, and allowed some to pass into the feeder. This could not be if the steam was much more than one-tenth weaker than air. By grasping this pipe in his hand during the rise of the piston, he could guess very well whereabouts the surface of the hot water in it rested during the motion, and he never found it supported so high as four feet. Therefore the steam in the cylinder had at least eight-ninths of

Steam-Engine.

of the elafticity of the air. Mr Buat, in his examination of an engine which is erected at Montrelaix, in France, by an Englifh engineer, and has always been confidered as the pattern in that country, finds it neceffary to fuppofe a much greater variation in the ftrength of the fteam, and fays, that it muft have been one-fifth ftronger and one-fifth weaker than common air. But this engine has not been nearly fo perfect. Its lift was not more than one-half of the preffure of the atmofphere, and it made but nine ftrokes in a minute.—At W is a valve covering the mouth of a fmall pipe, and furrounded with a cup containing water to keep it air-tight. This allows the air to efcape which had been extricated from the water of laft injection. It is driven out by the firft ftrong puff of fteam which is admitted into the cylinder, and makes a noife in its exit. The valve is therefore called the fnifting-valve.

To finifh our defcription, we obferve, that befides the fafety valve 9 (called the PUPPET CLACK), which is loaded with about 3 pounds on the fquare inch (though the engine will work very well with a load of 1 or 2 pounds), there is another DISCHARGER 10,10, having a clack at its extremity fupported by a cord. Its ufe is to difcharge the fteam without doors, when the machine gives over working. There is alfo a pipe SI near the bottom of the boiler, by which it may be emptied when it needs repairs or cleanfing.

There are two fmall pipes 11,11, and 12,12, with cocks called GAGE-PIPES. The firft defcends to within two inches of the furface of the water in the boiler, and the fecond goes about 2 inches below that furface. If both cocks emit fteam, the water is too low, and requires a recruit. If neither give fteam, it is too high, and there is not fufficient room above it for a collection of fteam. Laftly, there is a filling pipe Q, by which the boiler may be filled when the machine is to be fet to work.

29 This form of the engine has been continued for many years, the only change being the pofition of the boiler.

The engine has continued in this form for many years. The only remarkable change introduced has been the manner of placing the boiler. It is no longer placed below the cylinder, but at one fide, and the fteam is introduced by a pipe from the top of the boiler into a flat box immediately below the cylinder. The ufe of this box is merely to lodge the regulator, and give room for its motions. This has been a very confiderable improvement. It has greatly reduced the height of the building. This was formerly a tower. The wall which fupported the beam could hardly be built with fufficient ftrength for withftanding the violent fhocks which were repeated without ceafing; and the buildings feldom lafted more than a very few years. But the boiler is now fet up in an adjoining fhed, and the gudgeons of the main beam reft on the top of upright pofts, which are framed into the joifts which fupport the cylinder. Thus the whole moving parts of the machine are contained in one compact frame of carpentry, and have little or no connection with the flight walls of the building, which is merely a cafe to hold the machine, and protect it from the weather.

30 How to afcertain the moft advantageous proportion between the moving power and the load.

It is now time to inquire what is to be expected from this machine, and to afcertain the moft advantageous proportion between the moving power and the load that is to be laid on the machine.

It may be confidered as a great pulley, and is indeed fometimes fo conftructed, the arches at the ends of the working beam being completed to a circle. It muft be unequally loaded that it may move. It is loaded, during the working ftroke, by the preffure of the atmofphere on the pifton fide, and by the column of water to be raifed and the pump-gear on the pump fide.—During the returning ftroke it is loaded, on the pifton fide, by a fmall part of the atmofpheric preffure, and on the pump fide by the pump gear acting as a counter weight. The load during the working ftroke muft therefore confift of the column of water to be raifed and this counter weight. The performance of the machine is to be meafured only by the quantity of water raifed in a given time to a given height. It varies, therefore, in the joint proportion of the weight of the column of water in the pumps, and the number of ftrokes made by the machine in a minute. Each ftroke confifts of two parts, which we have called the working and the returning ftroke. It does not, therefore, depend fimply on the velocity of the working ftroke and the quantity of water raifed by it. If this were all that is to be attended to, we know that the weight of the column of water fhould be nearly $\frac{2}{3}$ths of the preffure of the atmofphere, this being the proportion which gives the maximum in the common pulley. But the time of the returning ftroke is a neceffary part of the whole time elapfed, and therefore the velocity of the returning ftroke equally merits attention. This is regulated by the counter weight. The number of ftrokes per minute does not give an immediate proof of the goodnefs of the engine. A fmall load of water and a great counter weight will enfure this, becaufe thefe conditions will produce a brifk motion in both directions.—The proper adjuftment of the preffure of the atmofphere on the pifton, the column of water to be raifed, and the counter weight, is a problem of very great difficulty; and mathematicians have not turned much of their attention to the fubject, although it is certainly the moft interefting queftion that practical mechanics affords them.

31 Mr Boffut's folution,

Mr Boffut has folved it very fhortly and fimply, upon this fuppofition, that the working and returning ftroke fhould be made in equal times. This, indeed, is generally aimed at in the erection of thefe machines, and they are not reckoned to be well arranged if it be otherwife. We doubt of the propriety of the maxim. Suppofing, however, this condition for the prefent, we may compute the loadings of the two ends of the beam as follows. Let a be the length of the inner arm of the working beam, or that by which the great pifton is fupported. Let b be the outer arm carrying the pump rods, and let W be a weight equivalent to all the load which is laid on the machine. Let c^2 be the area of the pifton; let H be the height of a column of water having c^2 for its bafe, and being equal in weight to the preffure exerted by the fteam on the under fide of the pifton; and let h be the preffure of the atmofphere on the fame area, or the height of a column of water of equal weight. It is evident that both ftrokes will be performed in equal times, if $h\,c^2\,a - W\,b$ be equal to $(h - H)\,c^2\,a + W\,b$. The firft of thefe quantities is the energy of the machine during the working ftroke, and the fecond expreffes the fimilar energy during the returning ftroke. This equation gives us $W = \frac{2\,h\,c^2\,a - H\,c^2\,a}{2\,b} = \frac{(2\,h - H)\,c^2\,a}{2\,b}$. If we

Steam-Engine.

we suppose the arms of the lever equal and $H=h$, we have $W=c^2\frac{h}{2}$; that is, the whole weight of the outer end of the beam should be half the pressure of the air on the great piston. This is nearly the usual practice; and the engineers express it by saying, that the engine is loaded with seven or eight pounds on the square inch. This has been found to be nearly the most advantageous load. This way of expressing the matter would do well enough, if the maxim were not founded on erroneous notions, which hinder us from seeing the state of the machine, and the circumstances on which its improvement depends. The piston bears a pressure of 15 pounds, it is said, on the square inch, if the vacuum below it be perfect; but as this is far from being the case, we must not load it above the power of its vacuum, which very little exceeds eight pounds. But this is very far from the truth. When the cylinder is tight, the vacuum is not more than $\frac{1}{30}$th deficient, when the cylinder is cooled by the injection to the degree that is every day practicable, and the piston really bears during its descent a pressure very near to 14 pounds on the inch. The load must be diminished, not on account of the imperfect vacuum, but to give the machine a reasonable motion. We must consider not only the moving force, but also the quantity of matter to be put in motion. This is so great in the steam-engine, that even if it were balanced, that is, if there were suspended on the piston arm a weight equal to the whole column of water and the counter weight, the full pressure of the atmosphere on the steam piston would not make it move twice as fast as it does.

32 founded on an erroneous maxim,

33 and faulty in another respect.

This equation by Mr Bossut is moreover essentially faulty in another respect. The W in the first member is not the same with the W in the second. In the first it is the column of water to be raised, together with the counter weight. In the second it is the counter weight only. Nor is the quantity H the same in both cases, as is most evident. The proper equation for ensuring the equal duration of the two strokes may be had in the following manner. Let it be determined by experiment what portion of the atmospheric pressure is exerted on the great piston during its descent. This depends on the remaining elasticity of the steam. Suppose it $\frac{9}{10}$ths: this we may express by $a\,h$, a being $=\frac{9}{10}$ths. Let it also be determined by experiment what portion of the atmospheric pressure on the piston remains unbalanced by the steam below it during its ascent. Suppose this $\frac{1}{10}$th, we may express this by $b\,h$. Then let W be the weight of the column of water to be raised, and c the counter weight. Then, if the arms of the beam are equal, we have the energy during the working stroke $=a\,h-W-c$, and during the returning stroke it is $=c-b\,h$. Therefore $c-b\,h=a\,h-W-c$; and $c=\frac{h(a+b)-W}{2}$; which, on the above supposition of the values of a and b, gives us $c=\frac{h-W}{2}$. We shall make some use of this equation afterwards; but it affords us no information concerning the most advantageous proportion of h and W, which is the material point.

34 Another way of considering the matter.

We must consider this matter in another way: And that we may not involve ourselves in unnecessary difficulties, let us make the case as simple as possible, and suppose the arms of the working-beam to be of equal length.

We shall first consider the adjustment of things at the outer end of the beam.

35 Adjustment of things at the outer end of the beam considered.

Since the sole use of the steam is to give room for the action of the atmospheric pressure by its rapid condensibility, it is admitted into the cylinder only to allow the piston to rise again, but without giving it any impulse. The pump-rods must therefore be returned to the bottom of the working barrels by means of a preponderancy at the outer end of the beam. It may be the weight of the pump-rods themselves, or may be considered as making part of this weight. A weight at the end of the beam will not operate on the rods which are suspended there by chains, and it must therefore be attached to the rods themselves, but above their respective pump-barrels, so that it may not lose part of its efficacy by immersion in the water. We may consider the whole under the notion of the pump-gear, and call it p. Its office is to depress the pump-rods with sufficient velocity, by overcoming the resistances arising from the following causes.

1. From the inertia of the beams and all the parts of the apparatus which are in motion during the descent of the pump-rods.

2. From the loss of weight sustained by the immersion of the pump-rods in water.

3. From the friction of all the pistons and the weight of the plug-frame.

4. From the resistance to the piston's motion, arising from the velocity which must be generated in the water in passing through the descending pistons.

The sum of all these resistances is equal to the pressure of some weight (as yet unknown), which we may call m.

When the pump-rods are brought up again, they bring along with them a column of water, whose weight we may call w.

It is evident that the load which must be overcome by the pressure of the atmosphere on the steam piston consists of w and p. Let this load be called L, and the pressure of the air be called P.

If p be $=$ L, no water will be raised; if p be $=o$, the rods will not descend: therefore there is some intermediate value of p which will produce the greatest effect.

In order to discover this, let g be the fall of a heavy body in a second.

The descending mass is p: but it does not descend with its full weight; because it is overcoming a set of resistances which are equivalent to a weight m, and the moving force is $p-m$. In order to discover the space through which the rods will descend in a second, when urged by the force $p-m$ (supposed constant, notwithstanding the increase of velocity, and consequently of m), we must institute this proportion $p:p-m=g:\frac{g(p-m)}{p}$.

The fourth term of this analogy is the space required.

Let t be the whole time of the descent in seconds. Then $1^2:t^2=\frac{g(p-m)}{p}:\frac{t^2g(p-m)}{p}$. This last term is is the whole deſcent or length of the ſtroke accompliſhed in the time t.

The weight of the column of water, which has now got above the piſton, is w, $=\text{L}-p$. This muſt be lifted in the next working ſtroke through the ſpace $\frac{t^2 g(p-m)}{p}$. Therefore the performance of the engine muſt be $\frac{t^2 g(p-m)(\text{L}-p)}{p}$.

That this may be the greateſt poſſible, we muſt conſider p as the variable quantity, and make the fluxion of the fraction $\frac{\overline{p-m}\times\overline{\text{L}-p}}{p}=o$.

This will be found to give us $p=\sqrt{\text{L}\,m}$; that is, the counter weight or preponderancy of the outer end of the beam is $=\sqrt{\text{L}\,m}$.

This gives us a method of determining m experimentally. We can diſcover by actual meaſurement the quantity L in any engine, it being equal to the unbalanced weights on the beam and the weight of the water in the pumps. Then $m=\frac{p^2}{\text{L}}$.

Alſo we have the weight of the column of water $=\text{L}-p$, $=\text{L}-\sqrt{\text{L}\,m}$.

When therefore we have determined the load which is to be on the outer end of the beam during the working ſtroke, it muſt be diſtributed into two parts, which have the proportion of $\sqrt{\text{L}\,m}$ to $\text{L}-\sqrt{\text{L}\,m}$. The firſt is the counter weight, and the ſecond is the weight of the column of water.

If m is a fraction of L, ſuch as an aliquot part of it; that is, if

$$m=\frac{\text{L}}{1},\ \frac{\text{L}}{4},\ \frac{\text{L}}{9},\ \frac{\text{L}}{16},\ \frac{\text{L}}{25},\ \text{\&c.}$$
$$p=\frac{\text{L}}{1},\ \frac{\text{L}}{2},\ \frac{\text{L}}{3},\ \frac{\text{L}}{4},\ \frac{\text{L}}{5},\ \text{\&c.}$$

The circumſtance which is commonly obtruded on us by local conſiderations is the quantity of water, and the depth from which it is to be raiſed; that is, w: and it will be convenient to determine every thing in conformity to this.

We ſaw that $w=\text{L}-\sqrt{\text{L}\,m}$. This gives us $\text{L}=\pm\sqrt{wm+\frac{m^2}{4}}+\frac{m}{2}+w$, and the counter weight $p=\sqrt{w\,m+\frac{m^2}{4}}+\frac{m}{2}$.

36 What proportion of moving force may be applied to the greateſt advantage.

Having thus aſcertained that diſtribution of the load on the outer end of the beam which produces the greateſt effect, we come now to conſider what proportion of moving force we muſt apply, ſo that it may be employed to the beſt advantage, or ſo that any expence of power may produce the greateſt performance. It will be ſo much the greater as the work done is greater, and the power employed is leſs; and will therefore be properly meaſured by the quotient of the work done divided by the power employed.

The work immediately done is the lifting up the weight L. In order to accompliſh this, we muſt employ a preſſure P, which is greater than L. Let it be $=\text{L}+y$; alſo let s be the length of the ſtroke.

If the maſs L were urged along the ſpace s by the force $\text{L}+y$, it would acquire a certain velocity, which we may expreſs by $\sqrt{s}$; but it is impelled only by the force y, the reſt of P being employed in balancing L. The velocities which different forces generate by impelling a body along the ſame ſpace are as the ſquare roots of the forces. Therefore $\sqrt{\text{L}+y} : \sqrt{y} = \sqrt{s} : \frac{\sqrt{s\,y}}{\sqrt{\text{L}+y}}$. The fourth term of this analogy expreſſes the velocity of the piſton at the end of the ſtroke. The quantity of motion produced will be had by multiplying this velocity by the maſs L. This gives $\frac{\text{L}\times\sqrt{s\,y}}{\sqrt{\text{L}+y}}$; and this divided by the power expended, or by $\text{L}+y$, gives us the meaſure of the performance; namely, $\frac{\text{L}\sqrt{s\,y}}{\overline{\text{L}+y}\times\sqrt{\text{L}+y}}$.

That this may be a maximum, conſider y as the variable quantity, and make the fluxion of this formula $=o$. This will give us $y=\frac{\text{L}}{2}$.

Now $\text{P}=\text{L}+y$, $=\text{L}+\frac{\text{L}}{2}$, $=\frac{3}{2}\,\text{L}$. Therefore the *whole* load on the outer end of the beam, conſiſting of the water and the counter weight, muſt be two-thirds of the preſſure of the atmoſphere on the ſteam piſton.

We have here ſuppoſed that the expenditure is the atmoſpheric preſſure; and ſo it is if we conſider it mechanically. But the expenditure of which we are ſenſible, and which we are anxious to employ to the beſt advantage, is fuel. Suppoſing this to be employed with the ſame judgement in all caſes, we are almoſt intitled, by what we now know of the production of ſteam, to ſay that the ſteam produced is proportional to the fuel expended. But the ſteam requiſite for merely filling the cylinder is proportional to the area of the piſton, and therefore to the atmoſpheric preſſure. The reſult of our inveſtigation therefore is ſtill juſt; but the ſteam waſted by condenſation on the ſides of the cylinder does not follow this ratio, and this is more than what is neceſſary for merely filling it. This deranges our calculations, and is in favour of large cylinders; but this advantage muſt be in a great meaſure compenſated by a ſimilar variation in the production of the ſteam; for in ſimilar boilers of greater dimenſions the fuel is leſs advantageouſly employed, becauſe the ſurface to which the fuel is applied does not increaſe in the ratio of the capacity, juſt as the ſurface of the cylinder which waſtes the ſteam. The rule may therefore be confided in as pretty exact.

37 Theſe reſults agree with the moſt ſucceſsful practice.

It is a ſatisfactory thing to obſerve theſe reſults agree very well with the moſt ſucceſsful practice. By many changes and trials engineers have eſtabliſhed maxims of conſtruction, which are probably not very far from the beſt. It is a pretty general maxim, that the load of water ſhould be one-half of the atmoſpheric preſſure. They call this loading the engine with $7\frac{1}{2}$ pounds on the inch, and they ſay that ſo ſmall a load is neceſſary on account of the imperfect vacuum. But we have now ſeen that it is neceſſary for giving a reaſonable velocity of motion. Since, in this practice, w is made $\frac{1}{2}$ or $\frac{6}{12}$ths of P, and L ſhould be $\frac{8}{12}$ths of P, and L is $=w+p$; it follows, that the counter weight ſhould be

Steam-Engine.

$\frac{1}{8}$th of P; and we have found this to be nearly the caſe in ſeveral very good engines.

It muſt be remarked, that in the preceding inveſtigation we introduced a quantity M to expreſs the reſiſtances to the motion of the engine. This was done in order to avoid a very troubleſome inveſtigation. The reſiſtances are of ſuch a nature as to vary with the velocity, and moſt of them as the ſquare of the velocity. This is the caſe with the reſiſtance ariſing from the motion of the water through the piſtons of the pumps, and that ariſing from the friction in the long lift during the working ſtroke. Had we taken the direct method, which is ſimilar to the determination of the motion through a medium which reſiſts in the duplicate ratio of the velocity, we muſt have uſed a very intricate exponential calculus, which few of our readers would have the patience to look at.

But the greateſt part of the quantity m ſuppoſes a motion already known, and its determination depends on this motion. We muſt now ſhow how its different component parts may be computed.

38 Reſiſtance to the motion of the engine computed.

1. What ariſes from the inertia of the moving parts is by far the moſt conſiderable portion of it. To obtain it, we muſt find a quantity of matter which, when placed at the end of the beam, will have the ſame momentum of inertia with that of the whole moving parts in their natural places. Therefore (in the returning ſtroke) add together the weight of the great piſton with its rod and chains; the pit pump-rods, chains, and any weight that is attached to them; the arch-heads and iron-work at the ends of the beam, and $\frac{4}{9}$ths of the weight of the beam itſelf; alſo the plug-beam with its arch-head and chain, multiplied by the ſquare of its diſtance from the axis, and divided by the ſquare of half the length of the beam; alſo the jack-head pump-rod, chain, and arch-head, multiplied by the ſquare of its diſtance from the axis, and divided by the ſquare of the half length of the beam. Theſe articles added into one ſum may be called M, and may be ſuppoſed to move with the velocity of the end of the beam. Suppoſe this beam to have made a ſix-foot ſtroke in two ſeconds, with an uniformly accelerated motion. In one ſecond it would have moved $1\frac{1}{2}$ feet, and would have acquired the velocity of three feet per ſecond. But in one ſecond gravity would have produced a velocity of 32 feet in the ſame maſs. Therefore the accelerating force, which has produced the velocity of three feet, is nearly $\frac{1}{11}$th of the weight. Therefore $\frac{M}{11}$ is the firſt conſtituent of m in the above inveſtigation. If the obſerved velocity is greater or leſs than three feet per ſecond, this value muſt be increaſed or diminiſhed in the ſame proportion.

The ſecond cauſe of reſiſtance, viz. the immerſion of the pump rods in water, is eaſily computed, being the weight of the water which they diſplace.

The third cauſe, the friction of the piſtons, &c. is almoſt inſignificant, and muſt be diſcovered by experiment.

The fourth cauſe depends on the ſtructure of the pumps. Theſe pumps, when made of a proper ſtrength, can hardly have the perforation of the piſton more than a fourth part of the area of the working-barrel; and the velocity with which the water paſſes through it is increaſed at leaſt $\frac{1}{4}$th by the contraction (ſee PUMP). The velocity of the water is therefore five times greater than that of the piſton. A piſton 12 inches diameter, and moving one foot per ſecond, meets with a reſiſtance equal to 20 pounds; and this increaſes as the ſquare of the diameter and as the ſquare of the velocity. If the whole depth of the pit be divided into ſeveral lifts, this reſiſtance muſt be multiplied by the number of lifts, becauſe it obtains in each pump.

Thus we make up the value of m; and we muſt acknowledge that the method is ſtill indirect, becauſe it ſuppoſes the velocity to be known.

We may obtain it more eaſily in another way, but ſtill with this circumſtance of being indirect. We found that p was equal to $\sqrt{\text{L}\,m}$, and conſequently $m=\frac{p^2}{\text{L}}$. Now in any engine L and p can always be had; and unleſs p deviates greatly from the proportion which we determined to be the beſt, the value of m thus obtained will not be very erroneous.

39 Obſervations concerning ſomething preſumed in the inveſtigation.

It was farther preſumed in this inveſtigation, that the motions both up and down were uniformly accelerated; but this cannot be the caſe when the reſiſtances increaſe with the velocity. This circumſtance makes very little change in the working-ſtroke, and therefore the theorem which determines the beſt relation of P to L may be confided in. The reſiſtances which vary with the velocity in this caſe are a mere trifle when compared with the moving power y. Theſe reſiſtances are, 1ſt, The ſtrangling of the water at the entry and at the ſtanding valve of each pump: This is about 37 pounds for a pump 12 inches diameter, and the velocity one foot per ſecond, increaſing in the duplicate ratio of the diameter and velocity. And, 2d, The friction of the water along the whole lift: This for a pump of the ſame ſize and with the ſame velocity, lifting 20 fathoms, is only about $2\frac{1}{2}$ pounds, and varies in the ſimple proportion of the diameter and the depth, and in the duplicate proportion of the velocity. The reſiſtance ariſing from inertia is greater than in the returning ſtroke; becauſe the M in this caſe muſt contain the momentum of the water both of the pit-pumps and the jackhead-pump: but this part of the reſiſtance does not affect the uniform acceleration. We may therefore confide in the propriety of the formula $y=\frac{\text{L}}{2}$. And we may obtain the velocity of this ſtroke at the end of a ſecond with great accuracy as follows. Let $2g$ be the velocity communicated by gravity in a ſecond, and the velocity at the end of the firſt ſecond of the ſteam piſton's deſcent will be ſomewhat leſs than $\frac{y}{\text{M}}\,2g$; where M expreſſes the inertia of all the parts which are in motion during the deſcent of the ſteam piſton, and therefore includes L. Compute the two reſiſtances juſt mentioned for this velocity. Call this r. Then $\frac{y-\frac{1}{2}r}{\text{M}}\,2g$ will give another velocity infinitely near the truth.

But the caſe is very different in the returning ſtroke, and the proper ratio of p to L is not aſcertained with the ſame certainty: for the moving force p is not ſo great in proportion to the reſiſtance m; and therefore the acceleration of the motion is conſiderably affected by it, and the motion itſelf is conſiderably retarded, and in a very moderate time it becomes ſenſibly uniform: for it is preciſely ſimilar to the motion of a heavy body falling

Steam-Engine.

falling through the air, and may be determined in the manner laid down in the article *RESISTANCE of Fluids*, viz. by an exponential calculus. We ſhall content ourſelves here with ſaying, that the reſiſtances in the preſent caſe are ſo great that the motion would be to all ſenſe uniform before the piſtons have deſcended one-third of their ſtroke, even although there were no other circumſtance to affect it.

40
The motion affected by a circumſtance that deſerves particular conſideration.

But this motion is affected by a circumſtance quite unconnected with any thing yet conſidered, depending on conditions not mechanical, and ſo uncertain, that we are not yet able to aſcertain them with any preciſion; yet they are of the utmoſt importance to the good performance and improvement of the engine, and therefore deſerve a particular conſideration.

The counter weight has not only to puſh down the pump rods, but alſo to *drag* up the great piſton. This it cannot do unleſs the ſteam be admitted into the cylinder. If the ſteam be no ſtronger than common air, it cannot enter the cylinder except *in conſequence* of the piſton's being dragged up. If common air were admitted into the cylinder, ſome force would be required to drag up the piſton, in the ſame manner as it is required to draw up the piſton of a common ſyringe; for the air would ruſh through the ſmall entry of the cylinder in the ſame manner as through the ſmall nozzle of the ſyringe. Some part of the atmoſpheric preſſure is employed in driving in the air with ſufficient velocity to fill the ſyringe, and it is only with the remainder that the admitted air preſſes on the under ſurface of the ſyringe. Therefore ſome of the atmoſpheric preſſure on its upper ſurface is not balanced. This is felt by the hand which draws it up. The ſame thing muſt happen in the ſteam-engine, and ſome part of the counter weight is expended in drawing up the ſteam-piſton. We could tell how much is thus expended if we knew the denſity of the ſteam; for this would tell us the velocity with which its elaſticity would cauſe it to fill the cylinder. If we ſuppoſe it 12 times rarer than air, which it certainly is, and the piſton riſes to the top of the cylinder in two ſeconds, we can demonſtrate that it will enter with a velocity not leſs than 1400 feet per ſecond, whereas 500 feet is enough to make it maintain a denſity $\frac{9}{10}$ths of that of ſteam in equilibrio with the air. Hence it follows, that its elaſticity will not be leſs than $\frac{29}{30}$ths of the elaſticity of the air, and therefore not more than $\frac{1}{30}$th of counter weight will be expended in drawing up the ſteam-piſton.

But all this is on the ſuppoſition that there is an unbounded ſupply of ſteam of undiminiſhed elaſticity. This is by no means the caſe. Immediately before opening the ſteam-cock, the ſteam was iſſuing through the ſafety-valve and all the crevices in the top of the boiler, and (in good engines) was about $\frac{1}{10}$th ſtronger or more elaſtic than air. This had been gathering during ſomething more than the deſcent of the piſton, viz. in about three ſeconds. The piſton riſes to the top in about two ſeconds; therefore about twice and a half as much ſteam as fills the dome of the boiler is now ſhared between the boiler and cylinder. The dome is commonly about ſix times more capacious than the cylinder. If therefore no ſteam is condenſed in the cylinder, the denſity of the ſteam, when the piſton has reached the top, muſt be about $\frac{15}{16}$ths of its former denſity, and ſtill more elaſtic than air. But as much ſteam is condenſed by the cold cylinder, its elaſticity muſt be leſs than this. We cannot tell how much leſs, both becauſe we do not know how much is thus condenſed, and becauſe by this diminution of its preſſure on the ſurface of the boiling water, it muſt be more copiouſly produced in the boiler; but an attentive obſervation of the engine will give us ſome information. The moment the ſteam-cock is opened we have a ſtrong puff of ſteam through the ſnifting valve. At this time, therefore, it is ſtill more elaſtic than air; but after this, the ſnifting valve remains ſhut during the whole riſe of the piſton, and no ſteam any longer iſſues through the ſafety-valve or crevices; nay, the whole dome of the boiler may be obſerved to ſink.

Steam-Engine.

41
The elaſticity of the ſteam during the aſcent of the piſton greatly diminiſhed.

Theſe facts give abundant proof that the elaſticity of the ſteam during the aſcent of the piſton is greatly diminiſhed, and therefore much of the counter weight is expended in dragging up the ſteam piſton in oppoſition to the unbalanced part of the atmoſpheric preſſure. The motion of the returning ſtroke is therefore ſo much deranged by this foreign and inappreciated circumſtance, that it would have been quite uſeleſs to engage in the intricate exponential inveſtigation, and we muſt ſit down contented with a leſs perfect adjuſtment of the counter weight and weight of water.—Any perſon who attends to the motion of a ſteam-engine will perceive that the deſcent of the pump-rods is ſo far from being accelerated, that it is nearly uniform, and frequently it is ſenſibly retarded towards the end. We learn by the way, that it is of the utmoſt importance not only to have a quick production of ſteam, but alſo a very capacious dome, or empty ſpace above the water in the boiler. In engines where this ſpace was but four or five times the capacity of the cylinder, we have always obſerved a very ſenſible check given to the deſcent of the pump-rods after having made half their ſtroke. This obliges us to employ a greater counter weight, which diminiſhes the column of water, or retards the working ſtroke; it alſo obliges us to employ a ſtronger ſteam, at the riſk of burſting the boiler, and increaſes the expence of fuel.

42
How to know the elaſticity of the ſteam in the cylinder.

It would be a moſt deſirable thing to get an exact knowledge of the elaſticity of the ſteam in the cylinder; and this is by no means difficult. Take a long glaſs tube exactly calibered, and cloſe at the farther end. Put a ſmall drop of ſome coloured fluid into it, ſo as to ſtand at the middle nearly.—Let it be placed in a long box filled with water to keep it of a conſtant temperature. Let the open end communicate with the cylinder, with a cock between. The moment the ſteam-cock is opened, open the cock of this inſtrument. The drop will be puſhed towards the cloſe end of the tube, while the ſteam in the cylinder is more elaſtic than the air, and it will be drawn the other way while it is leſs elaſtic, and, by a ſcale properly adapted to it, the elaſticity of the ſteam correſponding to every poſition of the piſton may be diſcovered. The ſame thing may be done more accurately by a barometer properly conſtructed, ſo as to prevent the oſcillations of the mercury.

43
Neceſſary alſo to know the ſtate of the cylinder during the deſcent of the piſton.

It is equally neceſſary to know the ſtate of the cylinder during the deſcent of the ſteam-piſton. We have hitherto ſuppoſed P to be the full preſſure of the atmoſphere on the area of the piſton, ſuppoſing the vacuum below it to be complete. But the inſpection of our table of elaſticity ſhows that this can never be the caſe, becauſe the cylinder is always of a temperature far above 32°. We have made many attempts to diſcover its temperature.

Steam-Engine.

perature. We have employed a thermometer in close contact with the side of the cylinder, which soon acquired a steady temperature: this was never less than 145°. We have kept a thermometer in the water which lies on the piston: this never sunk below 135°. It is probable that the cylinder within may be cooled somewhat lower; but for this opinion we cannot give any very satisfactory reason. Suppose it cooled down to 120°; this will leave an elasticity which would support three inches of mercury. We cannot think therefore that the unbalanced pressure of the atmosphere exceeds that of 27 inches of mercury, which is about $13\frac{1}{3}$d pounds on a square inch, or $10\frac{1}{2}$ on a circular inch. And this is the value which we should employ in the equation $P = L + y$. This question may be decided in the same way as the other, by a barometer connected with the inside of the cylinder.

And thus we shall learn the state of the moving forces in every moment of the performance, and the machine will then be as open to our examination as any water or horse mill; and till this be done, or something equivalent, we can only guess at what the machine is actually performing, and we cannot tell in what particulars we can lend it a helping hand. We are informed that Messrs Watt and Boulton have made this addition to some of their engines; and we are persuaded that, from the information which they have derived from it, they have been enabled to make the curious improvements from which they have acquired so much reputation and profit.

44 Quantity of cold water to be injected.

There is a circumstance of which we have as yet taken no notice, viz. the quantity of cold water injected. Here we confess ourselves unable to give any precise instructions. It is clear at first sight that no more than is absolutely necessary should be injected. It must generally be supplied by the engine, and this expends part of its power. An excess is much more hurtful by cooling the cylinder and piston too much, and therefore wasting steam during the next rise of the piston. But the determination of the proper quantity requires a knowledge, which we have not yet acquired, of the quantity of heat contained in the steam in a latent form. As much water must be injected as will absorb all this without rising near to the boiling temperature. But it is of much more importance to know how far we may cool the cylinder with advantage; that is, when will the loss of steam, during the next rise of the piston, compensate for the diminution of its elasticity during its present descent? Our table of elasticities shows us, that by cooling the cylinder to 120°, we still leave an elasticity equal to one-tenth of the whole power of the engine; if we cool it only to 140, we leave an elasticity of one-fifth; if we cool it to a blood-heat, we leave an elasticity of one-twentieth. It is extremely difficult to choose among these varieties. Experience, however, informs us, that the best engines are those which use the smallest quantities of injection water. We know an exceedingly good engine having a cylinder of 30 inches and a six feet stroke, which works with something less than one-fifth of a cubic foot of water at each injection; and we imagine that the quantity should be nearly in the proportion of the capacity of the cylinder. Desaguliers observed, that a very good engine, with a cylinder of 32 inches, worked with 300 inches of water at each injection, which does not much exceed one-sixth of a cubic foot. Mr Watt's observations, by means of the barometer, must have given him much valuable information in this particular, and we hope that he will not always withhold them from the public.

45 This examination, though not satisfactory, may direct the attention to the principal circumstances.

We have gone thus far in the examination, in order seemingly to ascertain the motion of the engine when loaded and balanced in any known manner, and in order to discover that proportion between the moving power and the load which will produce the greatest quantity of work. The result has been very unsatisfactory, because the computation of the returning stroke is acknowledged to be beyond our abilities. But it has given us the opportunity of directing the reader's attention to the leading circumstances in this inquiry. By knowing the internal state of the cylinder in machines of very different goodness, we learn the connection between the state of the steam and the performance of the machine; and it is very possible that the result of a full examination may be, that in situations where fuel is expensive, it may be proper to employ a weak steam which will expend less fuel, although less work is performed by it. We shall see this confirmed in the clearest manner in some particular employments of the new engines invented by Watt and Boulton.

In the mean time, we see that the equation which we gave from the celebrated Abbé Bossut, is in every respect erroneous even for the purpose which he had in view. We also see that the equation which we substituted in its place, and which was intended for determining that proportion between the counter-weight and the moving force, and the load which would render the working stroke and returning stroke of equal duration, is also erroneous, because these two motions are extremely different in kind, the one being nearly uniform, and the other nearly uniformly accelerated. This being supposed true, it should follow that the counter-weight should be reduced to one half; and we have found this to be very nearly true in some good engines which we have examined.

46 An erroneous maxim that the two motions are of equal duration.

We shall add but one observation more on this head. The practical engineers have almost made it a maxim, that the two motions are of equal duration. But the only reason which we have heard for the maxim, is, that it is aukward to see an engine go otherwise. But we doubt exceedingly the truth of this maxim, and, without being able to give any accurate determination, we think that the engine will do more work if the working stroke be made slower than the returning stroke. Suppose the engine so constructed that they are made in equal times; an addition to the counter-weight will accelerate the returning stroke and retard the working stroke. But as the counter-weight is but small in proportion to the unbalanced portion of the atmospheric pressure, which is the moving force of the machine, it is evident that this addition to the counter-weight must bear a much greater proportion to the counter-weight than it does to the moving force, and must therefore accelerate the returning stroke much more than it retards the working stroke, and the time of both strokes taken together must be diminished by this addition and the performance of the machine improved; and this must be the case as long as the machine is not extravagantly loaded. The best machine which we have seen, in respect of performance, raises a column of water whose weight is very nearly two-thirds of the pressure of the atmosphere atmofphere on the pifton, making 11 ftrokes of fix feet each per minute, and the working ftroke was almoft twice as flow as the other. This engine had worked pumps of 12 inches, which were changed for pumps of 14 inches, all other things remaining the fame. In its former ftate it made from 12 and a half to 13 and a half ftrokes per minute, the working ftroke being confiderably flower than the returning ftroke. The load was increafed, by the change of the pumps, nearly in the proportion to three to four. This had retarded the working ftroke; but the performance was evidently increafed in the proportion of 3×13 to 4×11, or of 39 to 44. About 300 pounds were added to the counterweight, which increafed the number of ftrokes to more than 12 per minute. No fenfible change could be obferved in the time of the working ftroke. The performance was therefore increafed in the proportion of 39 to 48. We have therefore no hefitation in faying, that the feemly equality of the two ftrokes is a facrifice to fancy. The engineer who obferves the working ftroke to be flow, fears that his engine may be thought feeble and unequal to its work; a fimilar notion has long mifled him in the conftruction of watermills, efpecially of overfhot mills; and, even now, he is fubmitting with hefitation and fear to the daily correction of experience.

It is needlefs to engage more deeply in fcientific calculations in a fubject where fo many of the data are fo very imperfectly underftood.

47 The load of work fhould not be lefs than 10 pounds for every fquare inch of the pifton.

We venture to recommend as a maxim of conftruction (fuppofing always a large boiler and plentiful fupply of pure fteam unmixed with air), that the load of work be not lefs than 10 pounds for every fquare inch of the pifton, and the counter-weight fo proportioned that the time of the returning ftroke may not exceed two-thirds of that of the working ftroke. A ferious objection may be made to this maxim, and it deferves mature confideration. Such a load requires the utmoft care of the machine, that no admiffion be given to the common air; and it precludes the poffibility of its working, in cafe the growth of water, or deepening the pit, fhould make a greater load abfolutely neceffary. Thefe confiderations muft be left to the prudence of the engineer. The maxim now recommended relates only to the beft actual performance of the engine.

48 Rules for computing the performance of the fteam-engine.

Before quitting this machine, it will not be amifs to give fome eafy rules, fanctioned by fuccefsful practice, for computing its performance. Thefe will enable any artift, who can go through fimple calculations, to fuit the fize of his engine to the tafk which it is to perform.

The circumftance on which the whole computation muft be founded is the quantity of water which muft be drawn in a minute, and the depth of the mine; and the performance which may be expected from a good engine is at leaft 12 ftrokes per minute of fix feet each, working againft a column of water whofe weight is equal to half of the atmofpheric preffure on the fteam-pifton, or rather to 7.64 pounds on every fquare inch of its furface.

It is moft convenient to eftimate the quantity of water in cubic feet, or its weight in pounds, recollecting that a cubic foot of water weighs $62\frac{1}{2}$ pounds. The depth of the pit is ufually reckoned in fathoms of fix feet, and the diameter of the cylinder and pump is ufually reckoned in inches.

Let Q be the quantity of water to be drawn per minute in cubical feet, and f the depth of the mine in fathoms; let c be the diameter of the cylinder, and p that of the pump; and let us fuppofe the arms of the beam to be of equal length.

1ft, To find the diameter of the pump, the area of the pifton in fquare feet is $p^2 \times \frac{0.7854}{144}$. The length of the column drawn in one minute is 12 times 6 or 72 feet, and therefore its folid contents is $p^2 \times \frac{72 \times 0.7854}{144}$ cubical feet, or $p^2 \times 0.3927$ cubical feet. This muft be equal to Q; therefore p^2 muft be $\frac{Q}{0.3927}$ or nearly $Q \times 2\frac{1}{2}$. Hence this practical rule: Multiply the cubic feet of water which muft be drawn in a minute by $2\frac{1}{2}$, and extract the fquare root of the product: this will be the diameter of the pump in inches.

Thus fuppofe that 58 cubic feet muft be drawn every minute; 58 multiplied by $2\frac{1}{2}$ gives 145, of which the fquare root is 12, which is the required diameter of the pump.

2. To find the proper diameter of the cylinder.

The pifton is to be loaded with 7.64 pounds on every fquare inch. This is equivalent to fix pounds on a circular inch very nearly. The weight of a cylinder of water an inch in diameter and a fathom in height is $2\frac{1}{21}$ pounds, or nearly two pounds. Hence it follows that $6c^2$ muft be made equal to $2fp^2$, and that c^2 is equal to $\frac{2fp^2}{6}$, or to $\frac{fp^2}{3}$.

Hence the following rule: Multiply the fquare of the diameter of the pump pifton (found as above) by the fathoms of lift, and divide the product by 3; the fquare root of the quotient is the diameter of the cylinder.

Suppofe the pit to which the foregoing pump is to be applied is 24 fathoms deep; then $\frac{24 \times 144}{3}$ gives 1152, of which the fquare root is 34 inches very nearly.

This engine conftructed with care will certainly do the work.

Whatever is the load of *water* propofed for the engine, let 10 be the pounds on every circular inch of the fteam pifton, and make $c^2 = p^2 \times \frac{2f}{m}$, and the fquare root will be the diameter of the fteam pifton in inches.

To free the practical engineer as much as poffible from all trouble of calculation, we fubjoin the following *TABLE of the Dimenfions and Power of the Steam Engine*, drawn up by Mr Beighton in 1717, and fully verified by practice fince that time. The meafure is in Englifh ale gallons of 282 cubic inches.

49
Mr Beighton's table of the dimensions and power of the steam-engine.

Diam. of pump.	Hhds in one yard.	Draws by a six feet stroke.	Weighs in one yard.	At 16 strokes per min.	Ditto in hogsheads.	Ditto per hour.	The depth to be drawn in yards.

Diameter of cylinder in inches.

The first part of the table gives the size of the pump suited to the growth of water. The second gives the size of the cylinder suited to the load of water. If the depth is greater than any in this table, take its fourth part, and double the diameter of the cylinder. Thus if 150 hogsheads are to be drawn in an hour from the depth of 100 fathoms, the last column of part first gives for 149.40 a pump of seven inches bore. In a line with this, under the depth of 50 yards, which is one-fourth of 100 fathoms, we find 20½, the double of which is 41 inches for the diameter of the cylinder.

It is almost impossible to give a general rule for strokes of different lengths, &c. but any one who professes the ability to erect an engine, should surely know as much arithmetic as will accommodate the rule now given to any length of stroke.

We venture to say, that no ordinary engineer can tell *à priori* the number per minute which an engine will give. We took 12 strokes of six feet each for a standard, which a careful engineer may easily accomplish, and which an employer has a right to expect, the engine being loaded with water to half the pressure of the atmosphere: if the load be less, there is some fault—an improper counter weight, or too little boiler, or leaks, &c. &c.

50
Mr Fitzgerald's method of converting its reciprocating motion into a continued rotatory motion.

Such is the state in which Newcomen's steam-engine had continued in use for 60 years, neglected by the philosopher, although it is the most curious object which human ingenuity has yet offered to his contemplation, and abandoned to the efforts of the unlettered artist. Its use has been entirely confined to the raising of water. Mr Keane Fitzgerald indeed published in the Philosophical Transactions a method of converting its reciprocating motion into a continued rotatory motion by employing the great beam to work a crank or a train of wheel-work. As the real action of the machine is confined to its working stroke, to accomplish this, it became necessary to connect with the crank or wheeled work a very large and heavy fly, which should accumulate in itself the whole pressure of the machine during its time of action, and therefore continue in motion, and urge forward the working machinery, while the steam engine was going through its inactive returning stroke. This will be the case, provided that the resistance exerted by the working machine during the whole period of the working and returning stroke of the steam-engine, together with the friction of both, does not exceed the whole pressure exerted by the steam-engine during its working stroke; and provided that the momentum of the fly, arising from its great weight and velocity, be very great, so that the resistance of the work during one returning stroke of the steam-engine do not make any very sensible dimunition of the velocity of the fly. This is evidently possible and easy. The fly may be made of any magnitude; and being exactly balanced round its axis, it will soon acquire any velocity consistent with the motion of the steam-engine. During the working stroke of the engine it is uniformly accelerated, and by its acquired momentum it produces in the beam the movement of the returning stroke; but in doing this, its momentum is shared with the inert matter of the steam-engine, and consequently its velocity diminished, but not entirely taken away. The next working stroke therefore, by pressing on it afresh, increases its remaining velocity by a quantity nearly equal to the whole that it acquired during the first stroke. We say *nearly*, but not quite equal, because the time of the second working stroke must be shorter than that of the first, on account of the velocity already in the machine. In this manner the fly will be more and more accelerated every succeeding stroke, because the pressure of the engine during the working stroke does more than restore to the fly the momentum which it lost in producing the returning movement of the steam-engine. Now suppose the working part of the machine to be added. The acceleration of the fly during each working stroke of the steam-engine will be less than it was before, because the impelling pressure is now partly employed in driving the working machine, and because the fly will lose more of its momentum during the returning stroke of the steam-engine, part of it being expended in driving the working machine. It is evident, therefore, that a time will

come

Steam-Engine.

come when the succeffive augmentation of the fly's velocity will ceafe; for, on the one hand, the continual acceleration diminifhes the time of the next working ftroke, and therefore the time of action of the accelerating power. The acceleration muft diminifh in the fame proportion; and on the other hand, the refiftance of the working machine generally, though not always, increafes with its velocity. The acceleration ceafes whenever the addition made to the momentum of the fly during a working ftroke of the fteam-engine is juft equal to what it lofes by driving the machine, and by producing the returning movement of the fteam-engine.

51 An important addition;

This muft be acknowledged to be a very important addition to the engine, and though fufficiently obvious, it is ingenious, and requires confiderable fkill and addrefs to make it effective (B).

The movement of the working machine, or mill of whatever kind, muft be in fome degree hobbling or unequal. But this may be made quite infenfible, by making the fly exceedingly large, and difpofing the greateft part of its weight in the rim. By thefe means its momentum may be made fo great, that the whole force required for driving the mill and producing the returning movement of the engine may bear a very fmall proportion to it. The diminution of its velocity will then be very trifling.

No counter weight is neceffary here, becaufe the returning movement is produced by the inertia of the fly. A counter weight may, however, be employed, and fhould be employed, viz. as much as will produce the returning movement of the fteam-engine. It will do this better than the fame force accumulated in the fly; for this force muft be accumulated in the fly by the intervention of rubbing parts, by which fome of it is loft; and it muft be afterwards returned to the engine with a fimilar lofs. But, for the fame reafon, it would be improper to make the counter weight alfo able to drive the mill during the returning ftroke.

52 but feldom or never adopted.

By this contrivance Mr Fitzgerald hoped to render the fteam-engine of moft extenfive ufe; and he, or others affociated with him, obtained a patent excluding all others from employing the fteam engine for turning a crank. They alfo publifhed propofals for erecting mills of all kinds driven by fteam engines, and ftated very fairly their powers and their advantages. But their propofals do not feem to have acquired the confidence of the public; for we do not know of any mill ever having been erected under this patent.

53 The great expenfe of fuel

The great obftacle to this extenfive ufe of the fteam-engine is the prodigious expenfe of fuel. An engine having a cylinder of four feet diameter, working night and day, confumes about 3400 chaldron (London) of good coals in a year.

This circumftance limits the ufe of fteam-engines exceedingly. To draw water from coal-pits, where they can be ftocked with unfaleable fmall coal, they are of universal employment: alfo for valuable mines, for fupplying a great and wealthy city with water, and a few other purpofes where a great expence can be borne, they are very proper engines; but in a thoufand cafes, where their unlimited powers might be vaftly ferviceable, the enormous expenfe of fuel completely excludes them. We cannot doubt but that the attention of engineers was much directed to every thing that could promife a diminution of this expenfe. Every one had his particular noftrum for the conftruction of his furnace, and fome were undoubtedly more fuccefsful than others. But fcience was not yet fufficiently advanced: It was not till Dr Black had made his beautiful difcovery of latent heat, that we could know the intimate relation between the heat expended in boiling off a quantity of water and the quantity of fteam that is produced.

54 limits the fteam-engines.

Much about the time of this difcovery, viz. 1763, Mr James Watt, eftablifhed in Glafgow in the commercial line, was amufing himfelf with repairing a working model of the fteam engine which belonged to the philofophical apparatus of the univerfity. Mr Watt was a perfon of a truly philofophical mind, eminently converfant in all branches of natural knowledge, and the pupil and intimate friend of Dr Black. In the courfe of the above-mentioned amufement many curious facts in the production and condenfation of fteam occurred to him; and among others, that remarkable fact which is always appealed to by Dr Black as the proof of the immenfe quantity of heat which is contained in a very minute quantity of water in the form of elaftic fteam. When a quantity of water is heated feveral degrees above the boiling point in a clofe digefter, if a hole be opened, the fteam rufhes out with prodigious violence, and the heat of the remaining water is reduced, in the courfe of three or four feconds, to the boiling temperature. The water of the fteam which has iffued amounts only to a very few drops; and yet thefe have carried off with them the whole excefs of heat from the water in the digefter.

55 Mr Watt difcovers that fteam contains an immenfe quantity of heat

56 in his attempts to find out a way to hufband this heat,

Since then a certain quantity of fteam contains fo great a quantity of heat, it muft expend a great quantity of fuel; and no conftruction of furnace can prevent this. Mr Watt therefore fet his invention to work to difcover methods of hufbanding this heat. The cylinder of his little model was heated almoft in an inftant, fo that it could not be touched by the hand. It could not be otherwife, becaufe it condenfed the vapour by abftracting its heat. But all the heat thus communicated to the cylinder, and wafted by it on furrounding bodies, contributed nothing to the performance of the engine,

(B) We do not recollect at prefent the date of this propofal of Mr Fitzgerald; but in 1781 the Abbé Arnal, canon of Alais in Languedoc, entertained a thought of the fame kind, and propofed it for working lighters in the inland navigations; a fcheme which has been fuccefsfully practifed (we are told) in America. His brother, a major of engineers in the Auftrian fervice, has carried the thing much farther, and applied it to manufactures; and the Aulic Chamber of Mines at Vienna has patronized the project: (See *Journal Encyclopedique*, 1781). But thefe fchemes are long pofterior to Mr Fitzgerald's patent, and are even later than the erection of feveral machines driven by fteam-engines which have been erected by Meffrs Watt and Boulton. We think it our duty to ftate thefe particulars, becaufe it is very ufual for our neighbours on the continent to affume the credit of Britifh inventions.

engine, and muſt be taken away at every injection, and again communicated and waſted. Mr Watt quickly underſtood the whole proceſs which was going on within the cylinder, and which we have conſidered ſo minutely, and ſaw that a very conſiderable portion of the ſteam muſt be waſted in warming the cylinder. His firſt attempts were made to aſcertain how much was thus waſted, and he found that it was not leſs than three or four times as much as would fill the cylinder and work the engine. He attempted to diminiſh this waſte by uſing wooden cylinders. But though this produced a ſenſible diminution of the waſte, other reaſons forced him to give them up. He then caſed his metal cylinders in a wooden caſe with light wood aſhes between. By this, and uſing no more injection than was abſolutely neceſſary for the condenſation, he reduced the waſte almoſt one half. But by uſing ſo ſmall a quantity of cold water, the inſide of the cylinder was hardly brought below the boiling temperature; and there conſequently remained in it a ſteam of very conſiderable elaſticity, which robbed the engine of a proportional part of the atmoſpherical preſſure. He ſaw that this was unavoidable as long as the condenſation

57 Diſcovers a method of condenſing the ſteam at a little diſtance from the cylinder,

was performed in the cylinder. The thought ſtruck him to attempt the condenſation in another place. His firſt experiment was made in the ſimpleſt manner. A globular veſſel communicated by means of a long pipe of one inch diameter with the bottom of his little cylinder of four inches diameter and 30 inches long. This pipe had a ſtop-cock, and the globe was immerſed in a veſſel of cold water. When the piſton was at the top, and the cylinder filled with ſtrong ſteam, he turned the cock. It was ſcarcely turned, nay he did not think it completely turned, when the ſides of his cylinder (only ſtrong tin-plate) were cruſhed together like an empty bladder. This ſurpriſed and delighted him. A new cylinder was immediately made of braſs ſufficiently thick, and nicely bored. When the experiment was repeated with this cylinder, the condenſation was ſo rapid, that he could not ſay that any time was expended in it. But the moſt valuable diſcovery was, that the vacuum in the cylinder was, as he hoped, almoſt perfect. Mr Watt found, that when he uſed water in the boiler purged of air by long boiling, nothing that was very ſenſibly inferior to the preſſure of the atmoſphere on the piſton could hinder it from coming quite down to the bottom of the cylinder. This alone was gaining a great deal, for in moſt engines the remaining elaſticity of the ſteam was not leſs than one-eighth of the atmoſpherical preſſure, and therefore took away one-eighth of the power of the engine.

58 And removes the difficulties which attended this improvement by means of pumps.

Having gained this capital point, Mr Watt found many difficulties to ſtruggle with before he could get the machine to continue its motion. The water produced from the condenſed ſteam, and the air which was extricated from it, or which penetrated through unavoidable leaks, behoved to accumulate in the condenſing veſſel, and could not be voided in any way ſimilar to that adopted in Newcomen's engine. He took another method: He applied pumps to extract both, which were worked by the great beam. The contrivance is eaſy to any good mechanic; only we muſt obſerve, that the piſton of the water-pump muſt be under the ſurface of the water in the condenſer, that the water may enter the pump by its own weight, becauſe there is no atmoſpherical preſſure there to force it in. We muſt alſo obſerve, that a conſiderable force is neceſſarily expended here, becauſe, as there is but one ſtroke for rarefying the air, and this rarefaction muſt be nearly complete, the air-pump muſt be of large dimenſions, and its piſton muſt act againſt the whole preſſure of the atmoſphere. Mr Watt, however, found that this force could be eaſily ſpared from his machine, already ſo much improved in reſpect of power.

59 Obſervations on the advantages of theſe diſcoveries.

Thus has the ſteam-engine received a very conſiderable improvement. The cylinder may be allowed to remain very hot; nay, boiling hot, and yet the condenſation be completely performed. The only elaſtic ſteam that now remains is the ſmall quantity in the pipe of communication. Even this ſmall quantity Mr Watt at laſt got rid of, by admitting a ſmall jet of cold water up this pipe to meet the ſteam in its paſſage to the condenſer. This both cooled this part of the apparatus in a ſituation where it was not neceſſary to warm it again, and it quickened the condenſation. He found at laſt that the ſmall pipe of communication was of itſelf ſufficiently large for the condenſation, and that no ſeparate veſſel, under the name of condenſer, was neceſſary. This circumſtance ſhows the prodigious rapidity of the condenſation. We may add, that unleſs this had been the caſe, his improvement would have been vaſtly diminiſhed; for a large condenſer would have required a much larger air-pump, which would have expended much of the power of the engine. By theſe means the vacuum below the piſton is greatly improved: for it will appear clear to any perſon who underſtands the ſubject, that as long as any part of the condenſer is kept of a low temperature, it will abſtract and condenſe the vapour from the warmer parts, till the whole acquires the elaſticity correſponding to the coldeſt part. By the ſame means much of the waſte is prevented, becauſe the cylinder is never cooled much below the boiling temperature. Many engines have been erected by Mr Watt in this form, and their performance gave univerſal ſatisfaction.

We have contented ourſelves with giving a very ſlight deſcription without a figure of this improved engine, becauſe we imagine it to be of very eaſy comprehenſion, and becauſe it is only a preparation for ſtill greater improvements, which, when underſtood, will at the ſame time leave no part of this more ſimple form unexplained.

60 Mr Watt makes the piſton deſcend by the force of ſteam.

During the progreſs of theſe improvements Mr Watt made many experiments on the quantity and denſity of the ſteam of boiling water. Theſe fully convinced him, that although he had greatly diminiſhed the waſte of ſteam, a great deal yet remained, and that the ſteam expended during the riſe of the piſton was at leaſt three times more than what would fill the cylinder. The cauſe of this was very apparent. In the ſubſequent deſcent of the piſton, covered with water much below the boiling temperature, the whole cylinder was neceſſarily cooled and expoſed to the air. Mr Watt's fertile genius immediately ſuggeſted to him the expedient of employing the elaſticity of the ſteam from the boiler to impel the piſton down the cylinder, in place of the preſſure of the atmoſphere; and thus he reſtored the engine to its firſt principles, making it an engine *really moved by ſteam*. As this is a new epoch in its hiſtory, we ſhall be more particular in the deſcription; at the ſame fame time ftill reftricting ourfelves to the effential circumftances, and avoiding every peculiarity which is to be found in the prodigious varieties which Mr Watt has introduced into the machines which he has erected, every individual of which has been adapted to local circumftances, or diverfified by the progrefs of Mr Watt's improvements.

61 Defcription of the machine after thefe improvements were added. Fig. 9.

Let A (fig. 9.) reprefent the boiler. This has received great improvements from his complete acquaintance with the procedure of nature in the production of fteam. In fome of his engines the fuel has been placed in the midft of the water, furrounded by an iron or copper veffel, while the exterior boiler was made of wood, which tranfmits, and therefore waftes the heat very flowly. In others, the flame not only plays round the whole outfide, as in common boilers, but alfo runs along feveral flues which are conducted through the midft of the water. By fuch contrivances the fire is applied to the water in a moft extenfive furface, and for a long time, fo as to impart to it the greateft part of its heat. So fkilfully was it applied in the Albion mills, that although it was perhaps the largeft engine in the kingdom, its unconfumed fmoke was inferior to that of a very fmall brew-houfe. In this fecond engine of Mr Watt, the top of the cylinder is fhut up by a ftrong metal plate *g h*, in the middle of which is a collar or box of leathers *k l*, formed in the ufual manner of a jack-head pump, through which the pifton rod PD, nicely turned and polifhed, can move up and down, without allowing any air to pafs by its fides. From the dome of the boiler proceeds a large pipe BCIOQ, which, after reaching the cylinder with its horizontal part BC, defcends parallel to its fide, fending off two branches, viz. IM to the top of the cylinder, and ON to its bottom. At I is a puppet valve opening from below upwards. At L, immediately below this branch, there is a fimilar valve, alfo opening from below upwards. The pipe defcends to Q, near the bottom of a large ciftern *c d e f*, filled with cold water conftantly renewed. The pipe is then continued horizontally along the bottom of this ciftern (but not in contact), and terminates at R in a large pump ST. The pifton S has clack valves opening upwards, and its rod S *s*, paffing through a collar of leathers at T, is fufpended by a chain to a fmall arch head on the outer arm of the beam. There is a valve R in the bottom of this pump, as ufual, which opens when preffed in the direction QR, and fhuts againft a contrary preffure. This pump delivers its contents into another pump XY, by means of the fmall pipe *t* X, which proceeds from its top. This fecond pump has a valve at X, and a clack in its pifton Z as ufual, and the pifton rod Z *z* is fufpended from another arch head on the outer arm of the beam. The two valves I and L are opened and fhut by means of fpanners and handles, which are put in motion by a plug frame, in the fame manner as in Newcomen's engine.

Laftly, there may be obferved a crooked pipe *a b o*, which enters the upright pipe laterally a little above Q. This has a fmall jet hole at *o*; and the other end *a*, which is confiderably under the furface of the water of the condenfing ciftern, is covered with a puppet valve *v*, whofe long ftalk *v u* rifes above the water, and may be raifed or lowered by hand or by the plug beam. The valves R and X, and the clacks in the piftons S and Z, are opened or fhut by the preffures to which they are immediately expofed.

This figure is not an exact copy of any of Mr Watt's engines, but has its parts fo difpofed that all may come diftinctly into view, and exactly perform their various functions. It is drawn in its quiefcent pofition, the outer end of the beam preponderating by the counter weight, and the pifton P at the top of the cylinder, and the piftons S and Z in their loweft fituations.

In this fituation let us fuppofe that a vacuum is (by any means) produced in all the fpace below the pifton, the valve I being fhut. It is evident that the valve R will alfo be fhut, as alfo the valve *v*. Now let the valve I be opened. The fteam from the boiler, as elaftic as common air, will rufh into the fpace above the pifton, and will exert on it a preffure as great as that of the atmofphere. It will therefore prefs it down, raife the outer end of the beam, and caufe it to perform the fame work as an ordinary engine.

When the pifton P has reached the bottom of the cylinder, the plug frame fhuts the valve I, and opens L. By fo doing the communication is open between the top and bottom of the cylinder, and nothing hinders the fteam which is above the pifton from going along the paffage MLON. The pifton is now equally affected on both fides by the fteam, even though a part of it is continually condenfed by the cylinder, and in the pipe IOQ. Nothing therefore hinders the pifton from being dragged up by the counter weight, which acts with its whole force, undiminifhed by any remaining unbalanced elafticity of fteam. Here therefore this form of the engine has an advantage (and by no means a fmall one) over the common engines, in which a great part of the counter weight is expended in overcoming unbalanced atmofpheric preffure.

Whenever the pifton P arrives at the top of the cylinder, the valve L is fhut by the plug frame, and the valves I and *v* are opened. All the fpace below the pifton is at this time occupied by the fteam which came from the upper part of the cylinder. This being a little wafted by condenfation, is not quite a balance for the preffure of the atmofphere. Therefore, during the afcent of the pifton, the valve R was fhut, and it remains fo. When, therefore, the valve *v* is opened, the cold water of the ciftern muft fpout up through the hole *o*, and condenfe the fteam. To this muft be added the coldnefs of the whole pipe OQS. As faft as it is condenfed, its place is fupplied by fteam from the lower part of the cylinder. We have already remarked, that this fucceffive condenfation is accomplifhed with aftonifhing rapidity. In the mean time, fteam from the boiler preffes on the upper furface of the pifton. It muft therefore defcend as before, and the engine muft perform a fecond working ftroke.

But in the mean time the injection water lies in the bottom of the pipe OQR, heated to a confiderable degree by the condenfation of the fteam; alfo a quantity of air has been difengaged from it and from the water in the boiler. How is this to be difcharged ?—This is the office of the pumps ST and XY. The capacity of ST is very great in proportion to the fpace in which the air and water are lodged. When, therefore, the pifton S has got to the top of its courfe, there muft be a vacuum in the barrel of this pump, and the water and air muft open the valve R and come into it. When the

pifton

pifton S comes down again in the next returning ftroke, this water and air gets through the valve of the pifton; and in the next working ftroke they are difcharged by the pifton into the pump XY, and raifed by its pifton. The air efcapes at Y, and as much of the water as is neceffary is delivered into the boiler by a fmall pipe Y g to fupply its wafte. It is a matter of indifference whether the piftons S and Z rife with the outer or inner end of the beam, but it is rather better that they rife with the inner end. They are otherwife drawn here, in order to detach them from the reft and fhow them more diftinctly.

Such is Mr Watt's fecond engine. Let us examine its principles, that we may fee the caufes of its avowed

62

and great fuperiority over the common engines.

Caufes of its fuperiority over common engines are, the full operation of the counter-weight,

We have already feen one ground of fuperiority, the full operation of the counter weight. We are authorifed by careful examination to fay, that in the common engines at leaft one-half of the counter weight is expended in counteracting an unbalanced preffure of the air on the pifton during its afcent. In many engines, which are not the worft, this extends to $\frac{1}{3}$th of the whole preffure. This is evident from the examination of the engine at Montrelaix by Boffut. This makes a very great counter weight neceffary, which exhaufts a proportional part of the moving force.

63

and great faving of fteam.

But the great advantage of Mr Watt's form is the almoft total annihilation of the wafte of fteam by condenfation in the cylinder. The cylinder is always boiling hot, and therefore perfectly dry. This muft be evident to any perfon who underftands the fubject. By the time that Mr Watt had completed his improvements, his experiments on the production of fteam had given him a pretty accurate knowledge of its denfity; and he found himfelf authorized to fay, that the quantity of fteam employed did not exceed twice as much as would fill the cylinder, fo that not above one-half was unavoidably wafted. But before he could bring the engine to this degree of perfection, he had many difficulties to overcome: He inclofed the cylinder in an outer wooden cafe at a fmall diftance from it. This diminifhed the expence of heat by communication to furrounding bodies. Sometimes he allowed the fteam from the boiler to occupy this interval. This undoubtedly prevented all diffipation from the inner cylinder; but in its turn it diffipated much heat by the outer cafe, and a very fenfible condenfation was obferved between them. This has occafioned him to omit this circumftance in fome of his beft engines. We believe it was omitted in the Albion mills.

The greateft difficulty was to make the great pifton tight. The old and effectual method, by water lying on it, was inadmiffible. He was therefore obliged to have his cylinders moft nicely bored, perfectly cylindrical, and finely polifhed; and he made numberlefs trials of different foft fubftances for packing his pifton, which fhould be tight without enormous friction, and which fhould always remain fo, in a fituation perfectly dry, and hot almoft to burning.

After all that Mr Watt has done in this refpect, he thinks that the greateft part of the wafte of fteam which he ftill perceives in his engines arifes from the unavoidable efcape by the fides of the pifton during its defcent.

But the fact is, that an engine of this conftruction, of the fame dimenfions with a common engine, making the fame number of ftrokes of the fame extent, does not confume above one-fourth part of the fuel that is confumed by the beft engines of the common form. It is alfo a very fortunate circumftance, that the performance of the engine is not immediately deftroyed, nor indeed fenfibly diminifhed, by a fmall want of tightnefs in the pifton. In the common engine, if air get in, in this way, it immediately puts a ftop to the work; but although even a confiderable quantity of fteam get paft the pifton during its defcent, the rapidity of condenfation is fuch, that hardly any diminution of preffure can be obferved. 64

Another valuable property of it.

Mr Watt's penetration foon difcovered another moft valuable property of this engine. When an engine of the common form is erected, the engineer muft make an accurate eftimate of the work to be performed, and muft proportion his engine accordingly. He muft be careful that it be *fully* able to execute its tafk; but its power muft not exceed its load in any extravagant degree. This would produce a motion which is too rapid, and which, being alternately in oppofite directions, would occafion jolts which no building or machinery could withftand. Many engines have been fhattered by the pumps drawing air, or a pump-rod breaking; by which accidents the fteam-pifton defcends with fuch rapidity that every thing gives way. But in moft operations of mining, the tafk of the engine increafes, and it muft be fo conftructed at firft as to be able to bear this addition. It is very difficult to manage an engine that is much fuperior to its tafk; and the eafieft way is, to have it almoft full loaded, and to work it only during a few hours each day, and allow the pit water to accumulate during its repofe. This increafes the firft coft, and waftes fuel during the inaction of the engine. 65

is, that it can always be exactly fitted to the load which happens to be on it.

But this new engine can at all times be exactly fitted (at leaft during the working ftroke) to the load of work that then happens to be on it. We have only to adminifter fteam of a proper elafticity. At the firft erection the engine may be equal to twice its tafk, if the fteam admitted above the cylinder be equal to that of common boiling water; but when once the ebullition is fairly commenced, and the whole air expelled from all parts of the apparatus, it is evident, that by damping the fire, fteam of half this elafticity may be continually fupplied, and the water will continue boiling although its temperature does not exceed 185° of Fahrenheit's thermometer. This appears by infpecting our table of vaporous elafticity, and affords another argument for rendering that table more accurate by new experiments. We hope that Mr Watt will not withhold from the public the knowledge which he has acquired on this fubject. It may very poffibly refult from an accurate inveftigation, that it would be advifable to work our fteam-engines with weak fteams, and that the diminution of work may be more than compenfated by the diminution of fuel. It is more probable indeed, and it is Mr Watt's opinion, that the contrary is the cafe, and that it is much more economical to employ great heats. At any rate, the decifion of this queftion is of great importance for improving the engine; and we fee, in the mean time, that the engine can at all times be fitted fo as to perform its tafk with a moderate and manageable motion, and that as the tafk increafes we can increafe the power of the engine.

But

Steam-Engine.

66 One inconvenience

But the method now propoſed has a great inconvenience. While the ſteam is weaker than the atmoſphere, there is an external force tending to ſqueeze in the ſides and bottom of the boiler. This could not be reſiſted when the difference is conſiderable, and common air would ruſh in through every crevice of the boiler and ſoon choke the engine : it muſt therefore be given up.

67 remedied in ſome degree.

But the ſame effect will be produced by diminiſhing the paſſage for the ſteam into the cylinder. For this purpoſe, the puppet valve by which the ſteam enters the cylinder was made in the form of a long taper ſpigot, and it was lodged in a cone of the ſame ſhape ; conſequently the paſſage could be enlarged or contracted at pleaſure by the diſtance to which the inner cone was drawn up.

68 But the remedy attended with ſome difficulties;

In this way ſeveral engines were conſtructed, and the general purpoſe of ſuiting the power of the engine to its taſk was completely anſwered ; but (as the mathematical reader will readily perceive) it was extremely difficult to make this adjuſtment preciſe and conſtant. In a great machine like this going by jerks, it was hardly poſſible that every ſucceſſive motion of the valve ſhould be preciſely the ſame. This occaſioned very ſenſible irregularities in the motion of the engine, which increaſed and became hazardous when the joints worked looſe by long uſe.

69 which Mr Watt's fertile genius completely removed.

Mr Watt's genius, always fertile in reſources, found out a complete remedy for all theſe inconveniences. Making the valve of the ordinary form of a puppet clack, he adjuſted the button of its ſtalk or tail ſo that it ſhould always open full to the ſame height. He then regulated the pins of the plug-frame, in ſuch a manner that the valve ſhould ſhut the moment that the piſton had deſcended a certain proportion (ſuppoſe one-fourth, one-third, one-half, &c.) of the cylinder. So far the cylinder was occupied by ſteam as elaſtic as common air. In preſſing the piſton farther down, it behoved the ſteam to expand, and its elaſticity to diminiſh. It is plain that this could be done in any degree we pleaſe, and that the adjuſtment can be varied in a minute, according to the exigency of the caſe, by moving the plug pins.

In the mean time, it muſt be obſerved, that the preſſure on the piſton is continually changing, and conſequently the accelerating force. The motion therefore will no longer be uniformly accelerated : it will approach much faſter to uniformity ; nay, it may be retarded, becauſe although the preſſure on the piſton at the beginning of the ſtroke may exceed the reſiſtance of the load, yet when the piſton is near the bottom the reſiſtance may exceed the preſſure. Whatever may be the law by which the preſſure on the piſton varies, an ingenious mechanic may contrive the connecting machinery in ſuch a way that the chains or rods at the outer end of the beam ſhall continually exert the ſame preſſure, or ſhall vary their preſſure according to any law he finds moſt convenient. It is in this manner that the watchmaker, by the form of the fuzee, produces an equal preſſure on the wheel-work by means of a very unequal action of the main-ſpring. In like manner, by making the outer arch heads portions of a proper ſpiral inſtead of a circle, we can regulate the force of the beam at pleaſure.

Thus we ſee how much more manageable an engine is in this form than Newcomen's was, and alſo more eaſily inveſtigated in reſpect of its power in its various poſitions. The knowledge of this laſt circumſtance was of mighty conſequence, and without it no notion could be formed of what it could perform. This ſuggeſted to Mr Watt the uſe of the barometer communicating with the cylinder ; and by the knowledge acquired by theſe means has the machine been ſo much improved by its ingenious inventor.

We muſt not omit in this place one deduction made by Mr Watt from his obſervations, which may be called a diſcovery of great importance in the theory of the engine.

70 A diſcovery of Mr Watt of great importance in the theory of the engine. Fig. 10.

Let ABCD (fig. 10.) repreſent a ſection of the cylinder of a ſteam-engine, and EF the ſurface of its piſton. Let us ſuppoſe that the ſteam was admitted while EF was in contact with AB, and that as ſoon as it had preſſed it down to the ſituation EF the ſteam cock is ſhut. The ſteam will continue to preſs it down, and as the ſteam expands its preſſure diminiſhes. We may expreſs its preſſure (exerted all the while the piſton moves from the ſituation AB to the ſituation EF) by the line EF. If we ſuppoſe the elaſticity of the ſteam proportional to its denſity, as is nearly the caſe with air, we may expreſs the preſſure on the piſton in any other poſition, ſuch as KL or DC, by K l and D c, the ordinates of a rectangular hyperbola F l c, of which AE, AB are the aſſymptotes, and A the centre. The accumulated preſſure during the motion of the piſton from EF to DC will be expreſſed by the area EF c DE, and the preſſure during the whole motion by the area ABF c DA.

Now it is well known that the area EF c DE is equal to ABFE multiplied by the hyperbolic logarithm of $\frac{AD}{AE}, = L. \frac{AD}{AE}$, and the whole area ABF c DA is $= ABFE \times \left(1 + L. \frac{AD}{AE}\right)$.

Thus let the diameter of the piſton be 24 inches, and the preſſure of the atmoſphere on a ſquare inch be 14 pounds ; the preſſure on the piſton is 6333 pounds. Let the whole ſtroke be 6 feet, and let the ſteam be ſtopped when the piſton has deſcended 18 inches, or 1.5 feet. The hyperbolic logarithm of $\frac{6}{1.5}$ is 1.3862943. Therefore the accumulated preſſure ABF c DA is $= 6333 \times 2.3862943, = 15114$ pounds.

As few profeſſional engineers are poſſeſſed of a table of hyperbolic logarithms, while tables of common logarithms are or ſhould be in the hands of every perſon who is much engaged in mechanical calculations, let the following method be practiſed. Take the common logarithm of $\frac{AD}{AE}$, and multiply it by 2.3026 ; the product is the hyperbolic logarithm of $\frac{AD}{AE}$.

The accumulated preſſure while the piſton moves from AB to EF is 6333×1, or ſimply 6333 pounds. Therefore the ſteam while it expands into the whole cylinder adds a preſſure of 8781 pounds.

Suppoſe that the ſteam had got free admiſſion during the whole deſcent of the piſton, the accumulated preſſure would have been 6333×4, or 25332 pounds.

Here Mr Watt obſerved a remarkable reſult. The ſteam expended in this caſe would have been four times greater

Steam-Engine.

greater than when it was ftopped at one-fourth, and yet the accumulated preffure is not twice as great, being nearly five-thirds. One-fourth of the fteam performs nearly three-fifths of the work, and an equal quantity performs more than twice as much work when thus admitted during one-fourth of the motion.

This is a curious and an important information, and the advantage of this method of working a fteam-engine increafes in proportion as the fteam is fooner ftopped; but the increafe is not great after the fteam is rarefied four times. The curve approaches near to the axis, and fmall additions are made to the area. The expenfe of fuch great cylinders is confiderable, and may fometimes compenfate this advantage.

Let the fteam be ftopped at			Its performance is mult.

&c.			&c.

It is very pleafing to obferve fo many unlooked-for advantages refulting from an improvement made with the fole view of leffening the wafte of fteam by condenfation. While this purpofe is gained, we learn how to hufband the fteam which is not thus wafted. The engine becomes more manageable, and is more eafily adapted to every variation in its tafk, and all its powers are more eafily computed.

The active mind of its ingenious inventor did not ftop here: It had always been matter of regret that one-half of the motion was unaccompanied by any work. It was a very obvious thing to Mr Watt, that as the fteam admitted above the pifton preffed it down, fo fteam admitted below the pifton preffed it up with the fame force, provided that a vacuum were made on its upper fide. This was eafily done, by connecting the lower end of the cylinder with the boiler and the upper end with the condenfer.

Plate DIII. Fig. 11.

71 Defcription of Mr Watt's fteam-engine in its moft improved ftate.

Fig. 11. is a reprefentation of this conftruction exactly copied from Mr Watt's figure accompanying his fpecification. Here BB is a fection of the cylinder, furrounded at a fmall diftance by the cafe 1111. The fection of the pifton A, and the collar of leathers which embraces the pifton rod, gives a diftinct notion of its conftruction, of the manner in which it is connected with the pifton-rod, and how the packing of the pifton and collar contributes to make all tight.

From the top of the cylinder proceeds the horizontal pipe. Above the letter D is obferved the feat of the fteam valve, communicating with the box above it. In the middle of this may be obferved a dark fhaded circle. This is the mouth of the upper branch of the fteam pipe coming from the boiler. Beyond D, below the letter N, is the feat of the upper condenfing valve. The bottom of the cylinder is made fpherical, fitting the pifton, fo that they may come into entire contact. Another horizontal pipe proceeds from this bottom. Above the letter E is the feat of the lower fteam valve, opening into the valve box. This box is at the extremity of another fteam pipe marked C, which branches off from the upper horizontal part, and defcends obliquely, coming forward to the eye. The lower part is reprefented as cut open, to fhow its interior conformation. Beyond this fteam valve, and below the letter F, may be obferved the feat of the lower condenfing valve. A pipe defcends from hence, and at a fmall diftance below unites with another pipe GG, which comes down from the upper condenfing valve N. Thefe two eduction-pipes thus united go downwards, and open at L into a rectangular box, of which the end is feen at L. This box goes backward from the eye, and at its farther extremity communicates with the air-pump K, whofe pifton is here reprefented in fection with its butterfly valves. The pifton delivers the water and air laterally into another rectangular box M, darkly fhaded, which box communicates with the pump I. The pifton-rods of this and of the air-pump are fufpended by chains from a fmall arch head on the inner arm of the great beam. The lower part of the eduction-pipe, the horizontal box L, the air-pump K, with the communicating box M between it and the pump I, are all immerfed in the cold water of the condenfing ciftern. The box L is made flat, broad, and fhallow, in order to increafe its furface and accelerate the condenfation. But that this may be performed with the greateft expedition, a fmall pipe H, open below (but occafionally ftopped by a plug valve), is inferted laterally into the eduction-pipe G, and then divides into two branches; one of which reaches within a foot or two of the upper valve N, and the other approaches as near to the valve F.

Steam-Engine.

As it is intended by this conftruction to give the pifton a ftrong impulfe in both directions, it will not be proper to fufpend its rod by a chain from the great beam; for it muft not only pull down that end of the beam, but alfo pufh it upwards. It may indeed be fufpended by double chains like the piftons of the engines for extinguifhing fires; and Mr Watt has accordingly done fo in fome of his engines. But in his drawing from which this figure is copied, he has communicated the force of the pifton to the beam by means of a toothed rack OO, which engages or works in the toothed fector QQ on the end of the beam. The reader will underftand, without any farther explanation, how the impulfe given to the pifton in either direction is thus tranfmitted to the beam without diminution. The fly XX, with its pinion Y, which alfo works in the toothed arch QQ, may be fuppofed to be removed for the prefent, and will be confidered afterwards.

We fhall take the prefent opportunity of defcribing Mr Watt's method of communicating the force of the fteam-engine to any machine of the rotatory kind. VV reprefents the rim and arms of a very large and heavy metalline fly. On its axis is the concentric toothed wheel U. There is attached to the end of the great beam a ftrong and ftiff rod TT, to the lower end of which a toothed wheel W is firmly fixed by two bolts, fo that it cannot turn round. This wheel is of the fame fize and in the fame vertical plane with the wheel U; and an iron link or ftrap (which cannot be feen here, becaufe it is on the other fide of the two wheels) connects the centres of the two wheels, fo that the one cannot quit the other. The engine being in the pofition reprefented in the figure, fuppofe the fly to be turned once round by any external force in the direction of the darts. It is plain, that fince the toothed wheels cannot quit each other, being kept together by the

Steam-Engine.

the link, the inner half (that is, the half next the cylinder) of the wheel U will work on the inner half of the wheel W, fo that at the end of the revolution of the fly the wheel W muft have got to the top of the wheel U, and the outer end of the beam muft be raifed to its higheft pofition. The next revolution of the fly will bring the wheel W and the beam connected with it to their firft pofitions; and thus every two revolutions of the fly will make a complete period of the beam's reciprocating movements. Now, inftead of fuppofing the fly to drive the beam, let the beam drive the fly. The motions muft be perfectly the fame, and the afcent or defcent of the pifton will produce one revolution of the fly.

Fig. 12.

A fide view of this apparatus is given in fig. 12. marked by the fame letters of reference. This fhows the fituation of parts which were fore-fhortened in fig. 11. particularly the defcending branch C of the fteam-pipe, and the fituation and communications of the two pumps K and I. 8, 8 is the horizontal part of the fteam-pipe. 9 is a part of it whofe box is reprefented by the dark circle of fig. 11. D is the box of the fteam-clack; and the little circle at its corner reprefents the end of the axis which turns it, as will be defcribed afterwards. N is the place of the upper eduction valve. A part only of the upper eduction-pipe G is reprefented, the reft being cut off, becaufe it would have covered the defcending fteam-pipe CC. When continued down, it comes between the eye and the box E of the lower fteam-valve, and the box F of the lower eduction-valve.

Let us now trace the operation of this machine through all its fteps. Recurring to fig. 11. let us fuppofe that the lower part of the cylinder BB is exhaufted of all elaftic fluids; that the upper fteam-valve D and the lower eduction-valve F are open, and that the lower fteam-valve E and upper eduction-valve N are fhut. It s evident that the pifton muft be preffed toward the bottom of the cylinder, and muft pull down the end of the working beam by means of the toothed rack OO and fector QQ, caufing the other end of the beam to urge forward the machinery with which it is connected. When the pifton arrives at the bottom of the cylinder, the valves D and F are fhut by the plug frame, and E and N are opened. By this laft paffage the fteam gets into the eduction-pipe, where it meets with the injection water, and is rapidly condenfed. The fteam from the boiler enters at the fame time by E, and preffing on the lower fide of the pifton, forces it upwards, and by means of the toothed rack OO and toothed fector QQ forces up that end of the working beam, and caufes the other end to urge forward the machinery with which it is connected: and in this manner the operation of the engine may be continued for ever.

The injection water is continually running into the eduction-pipe, becaufe condenfation is continually going on, and therefore there is a continual atmofpheric preffure to produce a jet. The air which is difengaged from the water, or enters by leaks, is evacuated only during the rife of the pifton of the air-pump K. When this is very copious, it renders a very large air-pump neceffary; and in fome fituations Mr Watt has been obliged to employ two air-pumps, one worked by each arm of the beam. This in every cafe expends a very confiderable portion of the power, for the air-pump is always working againft the whole preffure of the atmofphere.

Steam-Engine.

It is evident that this form of the engine, by maintaining an almoft conftant and uninterrupted impulfion, is much fitter for driving any machinery of continued motion than any of the former engines, which were inactive during half of their motion. It does not, however, feem to have this fuperiority when employed to draw water: But it is equally fitted for this tafk. Let the engine be loaded with twice as much as would be proper for it if a fingle-ftroke engine, and let a fly be connected with it. Then it is plain that the power of the engine during the rife of the fteam-pifton will be accumulated in the fly; and this, in conjunction with the power of the engine during the defcent of the fteam-pifton, will be equal to the whole load of water.

In fpeaking of the fteam and eduction-valves, we faid that they were all puppet-valves. Mr Watt employed cocks, and alfo fliding-valves, fuch as the regulator or fteam-valves in the old engines. But he found them always lofe their tightnefs after a fhort time. This is not furprifing, when we confider that they are always perfectly dry, and almoft burning hot. He was therefore obliged to change them all for puppet-clacks, which, when truly ground and nicely fitted in their motions at firft, are not found to go out of order by any length of time. Other engineers now univerfally ufe them in the old form of the fteam-engine, without the fame reafons, and merely by fervile and ignorant imitation.

The way in which Mr Watt opens and fhuts thefe valves is as follows. Fig. 13. reprefents a clack with its feat and box. Suppofe it one of the eduction-valves. HH is part of the pipe which introduces the fteam, and GG is the upper part of the pipe which communicates with the condenfer. At EE may be obferved a piece more faintly fhaded than the furrounding parts. This is the feat of the valve, and is a brafs or bell-metal ring turned conical on the outfide, fo as to fit exactly into a conical part of the pipe GG. Thefe two pieces are fitted by grinding; and the cone being of a long taper, the ring fticks firmly in it, efpecially after having been there for fome time and united by ruft. The clack itfelf is a ftrong brafs plate D, turned conical on the edge, fo as to fit the conical or floping inner edge of the feat. Thefe are very nicely ground on each other with emery. This conical joining is much more obtufe than the outer fide of the ring; fo that although the joint is air-tight, the two pieces do not ftick ftrongly together. The clack has a round tail DG, which is freely moveable up and down in the hole of a crofs piece FF. On the upper fide of the valve is a ftrong piece of metal DC firmly joined to it, one fide of which is formed into a toothed rack. A is the fection of an iron axle which turns in holes in the oppofite fides of the valve-box, where it is nicely fitted by grinding, fo as to be air-tight. Collets of thick leather, well foaked in melted tallow and rofin, are fcrewed on the outfide of thefe holes to prevent all ingrefs of air. One end of this axis projects a good way without the box, and carries a fpanner or handle, which is moved by the plug-frame. To this axis is fixed a ftrong piece of metal B, the edge of which is formed into an arch of a circle having the axis A in its centre, and is cut into teeth, which work in the teeth

Fig. 13.

Steam-Engine.

teeth of the rack DC. K is a cover which is fixed by fcrews to the top of the box HJJH, and may be taken off in order to get at the valve when it needs repairs.

From this defcription it is eafy to fee that by turning the handle which is on the axis A, the fector B muft lift up the valve by means of its toothed rack DC, till the upper end of the rack touch the knob or button K. Turning the handle in the oppofite direction brings the valve down again to its feat.

This valve is extremely tight. But in order to open it for the paffage of the fteam, we muft exert a force equal to the preffure of the atmofphere. This in a large engine is a very great weight. A valve of fix inches diameter fuftains a preffure not lefs that 400 pounds. But this force is quite momentary, and hardly impedes the motion of the engine; for the inftant the valve is detached from its feat, although it has not moved the 100th part of an inch, the preffure is over. Even this little inconvenience has been removed by a delicate thought of Mr Watt. He has put the fpanner in fuch a pofition when it *begins* to raife the valve, that its mechanical energy is almoft infinitely great. Let QR (fig. 14.) be part of the plug-frame defcending, and P one of its pins juft going to lay hold of the fpanner NO moveable round the axis N. On the fame axis is another arm NM connected by a joint with the leader ML, which is connected alfo by a joint with the fpanner LA that is on the axis A of the fector within the valve-box. Therefore when the pin P pufhes down the fpanner NO, the arm NM moves fidewife and pulls down the fpanner AL by means of the connecting rod. Things are fo difpofed, that when the cock is fhut, LM and MN are in one ftraight line. The intelligent mechanic will perceive that, in this pofition, the force of the lever ONM is infuperable. It has this further advantage, that if any thing fhould tend to force open the valve, it would be ineffectual; for no force exerted at A, and tranfmitted by the rod LM, can poffibly pufh the joint M out of its pofition. Of fuch importance is it to practical mechanics, that its profeffors fhould be perfons of penetration as well as knowledge. Yet this circumftance is unheeded by hundreds who have fervilely copied from Mr Watt, as may be feen in every engine that is puffed on the public as a difcovery and an improvement. When thefe puppet-valves have been introduced into the common engine, we have not feen one inftance where this has been attended to; certainly becaufe its utility has not been obferved: and there is one fituation where it is of more confequence than in Mr Watt's engine, viz. in the injection-cock. Here the valve is drawn back into a box, where the water is fo aukwardly difpofed round it that it can hardly get out out of its way, and where the preffure even exceeds that of the atmofphere. Indeed this particular fubftitution of the button-valve for the cock is moft injudicious.

We poftponed any account of the office of the fly XX (fig. 11.), as it is not of ufe in an engine regulated by the fly VV. The fly XX is only for regulating the reciprocating motion of the beam when the fteam is not admitted during the whole defcent of the pifton. This it evidently muft render more uniform, accumulating a momentum equal to the whole preffure of the full fupply of fteam, and then fharing it with the beam during the reft of the defcent of the pifton.

When a perfon properly fkilled in mechanics and chemiftry reviews thefe different forms of Mr Watt's fteam-engine, he will eafily perceive them fufceptible of many intermediate forms, in which any one or more of the diftinguifhing improvements may be employed. The firft great improvement was the condenfation in a feparate veffel. This increafed the original powers of the engine, giving to the atmofpheric preffure and to the counter-weight their full energy; at the fame time the wafte of fteam is greatly diminifhed. The next improvement, by employing the preffure of the fteam inftead of that of the atmofphere, aimed only at a ftill farther diminution of the wafte; but was fertile in advantages, rendering the machine more manageable, and particularly enabling us at all times, and without trouble, to fuit the power of the engine to its load of work, however variable and increafing; and brought into view a very interefting propofition in the mechanical theory of the engine, viz. that the whole performance of a given quantity of fteam may be augmented by admitting it into the cylinder only during a part of the pifton's motion. Mr Watt has varied the application of this propofition in a thoufand ways; and there is nothing about the machine which gives more employment to the fagacity and judgement of the engineer. The third improvement of the double impulfe may be confidered as the finifhing touch given to the engine, and renders it as uniform in its action as any water-wheel. In the engine in its moft perfect form there does not feem to be above one-fourth of the fteam wafted by warming the apparatus; fo that *it is not poffible* to make it one-fourth part more powerful than it is at prefent. The only thing that feems fufceptible of confiderable improvement is the great beam. The enormous ftrains exerted on its arms require a proportional ftrength. This requires a vaft mafs of matter, not lefs indeed in an engine with a cylinder of 54 inches than three tons and a half, moving with the velocity of three feet in a fecond, which muft be communicated in about half a fecond. This mafs muft be brought into motion from a ftate of reft, muft again be brought to reft, again into motion, and again to reft, to complete the period of a ftroke. This confumes much power; and Mr Watt has not been able to load an engine with more than 10 or 11 pounds on the inch and preferve a fufficient quantity of motion, fo as to make 12 or 15 fix-feet ftrokes in a fecond. Many attempts have been made to leffen this mafs by ufing a light framed wheel, or a light frame of carpentry, in place of a folid beam. Thefe have generally been conftructed by perfons ignorant of the true fcientific principles of carpentry, and have fared accordingly. Mr Watt has made fimilar attempts; but found, that although at firft they were abundantly ftrong, yet after a fhort time's employment the ftraps and bolts with which the wooden parts were connected cut their way into the wood, and the framing grew loofe in the joints, and, without giving any warning, went to pieces in an inftant. A folid maffy fimple beam, of fufficient ftrength, bends, and fenfibly complains (as the carpenters exprefs it), before it breaks. In all great engines, therefore, fuch only are employed, and in fmaller engines he fometimes ufes caft-iron wheels or pulleys; nay, he frequently ufes no beam or equivalent whatever, but employs the fteam-pifton rod to drive the machinery to which the engine is applied.

72 Review of Mr Watt's three great improvements.

73 The only improvement now wanting is to ftrength-en the great beam.

We prefume that our thinking readers will not be difpleafed

Steam-Engine.

diſpleaſed with this rational hiſtory of the progreſs of this engine in the hands of its ingenious and worthy inventor. We owe it to the communications of a friend, well acquainted with him, and able to judge of his merits. The public ſee him always aſſociated with the no leſs celebrated mechanic and philoſopher Mr Boulton of Soho near Birmingham (ſee SOHO). They have ſhared the royal patent from the beginning; and the alliance is equally honourable to both.

74 Mr Watt aſſociated with Mr Boulton.

75 Whence their profits are derived in erecting engines.

The advantages derived from the patent-right ſhow both the ſuperiority of the engine and the liberal minds of the proprietors. They erect the engines at the expence of the employers, or give working drafts of all the parts, with inſtructions, by which any reſident engineer may execute the work. The employers ſelect the beſt engine of the ordinary kind in the kingdom, compare the quantities of fuel expended by each, and pay to Meſſrs Watt and Boulton one-third of the annual ſavings for a certain term of years. By this the patentees are excited to do their utmoſt to make the engine perfect; and the employer pays in proportion to the advantage he derives from it.

It may not be here improper to ſtate the actual performance of ſome of theſe engines, as they have been aſcertained by experiment.

76 What the actual performance of ſome of theſe engines is.

An engine having a cylinder of 31 inches in diameter, and making 17 double ſtrokes per minute, performs the work of forty horſes working night and day (for which three relays or 120 horſes muſt be kept), and burns 11,000 pounds of Staffordſhire coal per day. A cylinder of 19 inches, making 25 ſtrokes of 4 feet each per minute, performs the work of 12 horſes working conſtantly, and burns 3700 pounds of coals per day. A cylinder of 24 inches, making 22 ſtrokes of 5 feet, burns 5500 pounds of coals, and is equivalent to the conſtant work of 20 horſes. And the patentees think themſelves authorized by experience to ſay in general, that theſe engines will raiſe more than 20,000 cubic feet of water 24 feet high for every hundred weight of good pit-coal conſumed by them.

In conſequence of the great ſuperiority of Mr Watt's engines, both with reſpect to economy and manageableneſs, they have become of moſt extenſive uſe; and in every demand of manufacture on a great ſcale they offer us an indefatigable ſervant, whoſe ſtrength has no bounds. The greateſt mechanical project that ever engaged the attention of man was on the point of being executed by this machine. The States of Holland were treating with Meſſrs Watt and Boulton for draining the Haerlem Meer, and even reducing the Zuyder Zee: and we doubt not but that it will be accompliſhed whenever that unhappy nation has ſufficiently felt the difference between liberty and foreign tyranny. Indeed ſuch unlimited powers are afforded by this engine, that the engineer now thinks that no taſk can be propoſed to him which he cannot execute with profit to his employer.

77 Propoſed to drain the Haerlem Meer by the ſteam-engine.

78 The attempts to improve Mr Watt's engine in general of little advantage;

No wonder then that all claſſes of engineers have turned much of their attention to this engine; and ſeeing that it has done ſo much, that they try to make it do ſtill more. Numberleſs attempts have been made to improve Mr Watt's engine; and it would occupy a volume to give an account of them, whilſt that account would do no more than indulge curioſity. Our engineers by profeſſion are in general miſerably deficient in that accurate knowledge of mechanics and of chemiſtry which is neceſſary for underſtanding this machine; and we have not heard of one in this kingdom who can be put on a par with the preſent patentees in this reſpect. Moſt of the attempts of engineers have been made with the humbler view of availing themſelves of Mr Watt's diſcoveries, ſo as to conſtruct a ſteam-engine ſuperior to Newcomen's, and yet of a form ſufficiently different from Watt's to keep it without the reach of his patent. This they have in general accompliſhed by performing the condenſation in a place which, with a little ſtretch of fancy, not unfrequent in a court of law, may be called *part of the cylinder*.

79 and the ſucceſs of theſe has not injured the other.

The ſucceſs of moſt of theſe attempts has interfered ſo little with the intereſt of the patentees, that they have not hindered the erection of many engines which the law would have deemed encroachments. We think it our duty to give our opinion on this ſubject without reſerve. Theſe are moſt expenſive undertakings, and few employers are able to judge accurately of the merits of a project preſented to them by an ingenious artiſt. They may ſee the practicability of the ſcheme, by having a general notion of the expanſion and condenſation of ſteam, and they may be miſled by the ingenuity apparent in the conſtruction. The engineer himſelf is frequently the dupe of his own ingenuity; and it is not always diſhoneſty, but frequently ignorance, which makes him prefer his own invention or (as he thinks it) improvement. It is a moſt delicate engine, and requires much knowledge to ſee what does and what does not improve its performance. We have gone into the preceding minute inveſtigation of Mr Watt's progreſs with the expreſs purpoſe of making our readers fully maſters of its principles, and have more than once pointed out the real improvements, that they may be firmly fixed and always ready in the mind. By having recourſe to them, the reader may pronounce with confidence on the merits of any new conſtruction, and will not be deceived by the puffs of an ignorant or diſhoneſt engineer.

80 Exception in favour of Mr Hornblower.

We muſt except from this general criticiſm a conſtruction by Mr Jonathan Hornblower near Briſtol, on account of its ſingularity, and the ingenuity and real ſkill which appears in ſome particulars of its conſtruction. The following ſhort deſcription will ſufficiently explain its principle, and enable our readers to appreciate its merit.

Plate DIV. Description of his ſteam-engine.

A and B (fig. 15.) repreſent two cylinders, of which A is the largeſt. A piſton moves in each, having their rods C and D moving through collars at E and F. Theſe cylinders may be ſupplied with ſteam from the boiler by means of the ſquare pipe G, which has a flanch to connect it with the reſt of the ſteam-pipe. This ſquare part is repreſented as branching off to both cylinders. *c* and *d* are two cocks, which have handles and tumblers as uſual, worked by the plug-beam W. On the fore-ſide (that is, the ſide next the eye) of the cylinders is repreſented another communicating pipe, whoſe ſection is alſo ſquare or rectangular, having alſo two cocks *a*, *b*. The pipe Y, immediately under the cock *b*, eſtabliſhes a communication between the upper and lower parts of the ſmall cylinder B, by opening the cock *b*. There is a ſimilar pipe on the other ſide of the cylinder A, immediately under the cock *d*. When the cocks *c* and *a* are open, and the cocks *b* and *d* are ſhut, the ſteam from the boiler has free admiſſion into the upper part of the cylinder B, and the ſteam from

from the lower part of B has free admiſſion into the upper part of A; but the upper part of each cylinder has no communication with its lower part.

From the bottom of the great cylinder proceeds the eduction-pipe K, having a valve at its opening into the cylinder, which bends downwards, and is connected with the conical condenſer L (c). The condenſer is fixed on a hollow box M, on which ſtand the pumps N and O for extracting the air and water; which laſt runs along the trough T into a ciſtern U, from which it is raiſed by the pump V for recruiting the boiler, being already nearly boiling hot. Immediately under the condenſer there is a ſpigot valve at S, over which is a ſmall jet pipe, reaching to the bend of the eduction-pipe. The whole of the condenſing apparatus is contained in a ciſtern R of cold water. A ſmall pipe P comes from the ſide of the condenſer, and terminates on the bottom of the trough T, and is there covered with a valve Q, which is kept tight by the water that is always running over it. Laſtly, the pump-rods X cauſe the outer end of the beam to preponderate, ſo that the quieſcent poſition of the beam is that repreſented in the figure, the piſtons being at the top of the cylinders.

Suppoſe all the cocks open, and ſteam coming in copiouſly from the boiler, and no condenſation going on in L; the ſteam muſt drive out all the air, and at laſt follow it through the valve Q. Now ſhut the valves *b* and *d*, and open the valve S of the condenſer. The condenſation will immediately commence. There is now no preſſure on the under ſide of the piſton of A, and it immediately deſcends. The communication between the lower part of B and the upper part of A being open, the ſteam will go from B into the ſpace left by the piſton of A. It muſt therefore expand, and its elaſticity muſt diminiſh, and will no longer balance the preſſure of the ſteam above the piſton of B. This piſton therefore, if not withheld by the beam, would deſcend till it is in equilibrio, having ſteam of equal denſity above and below it. But it cannot deſcend ſo far; for the cylinder A is wider than B, and the arm of the beam at which its piſton hangs is longer than the arm which ſupports the piſton of B: therefore when the piſton of B has deſcended as far as the beam will permit it, the ſteam between the two piſtons occupies a larger ſpace than it did when both piſtons were at the tops of their cylinders. Its denſity, therefore, and its elaſticity, diminiſh as its bulk increaſes. It is therefore not a balance; for the ſteam on the upper ſide of B, and the piſton B, *pulls* at the beam with all the difference of theſe preſſures. The ſlighteſt view of the ſubject muſt ſhow the reader, that as the piſtons deſcend, the ſteam that is between them will grow continually rarer and leſs elaſtic, and that both piſtons will pull the beam downwards.

Suppoſe now that each has reached the bottom of its cylinder. Shut the cock *a* and the eduction cock at the bottom of A, and open the cocks *b* and *d*. The communication being now eſtabliſhed between the upper and lower part of each cylinder, nothing hinders the counter weight from raiſing the piſtons to the top. Let them arrive there. The cylinder B is at this time filled with ſteam of the ordinary denſity, and the cylinder A with an equal abſolute quantity of ſteam, but expanded into a larger ſpace.

Shut the cocks *b* and *d*, and open the cock *a*, and the eduction cock at the bottom of A; the condenſation will again operate, and the piſtons deſcend. And thus the operation may be repeated as long as ſteam is ſupplied; and one full of the cylinder B of ordinary ſteam is expended during each working ſtroke.

Let us now examine the power of this engine. It is evident, that when both piſtons are at the top of their reſpective cylinders, the active preſſure (that is, the difference of the preſſure on its two ſides) on the piſton of B is nothing, while that on the piſton of A is equal to the full preſſure of the atmoſphere on its area. This, multiplied by the length of the arm by which it is ſupported, gives its mechanical energy. As the piſtons deſcend, the preſſure on the piſton of B increaſes, while that on the piſton of A diminiſhes. When both are at the bottom, the preſſure on the piſton of B is at its maximum, and that on the piſton of A at its minimum.

Mr Hornblower ſaw that this muſt be a beneficial employment of ſteam, and preferable to the practice of condenſing it while its full elaſticity remained; but he has not conſidered it with the attention neceſſary for aſcertaining the advantage with preciſion.

Let a and b repreſent the areas of the piſtons of A and B, and let α and β be the lengths of the arms by which they are ſupported. It is evident, that when both piſtons have arrived at the bottoms of their cylinders, the capacities of the cylinders are as $a\,\alpha$ and $b\,\beta$. Let this be the ratio of m to 1. Let $g\,h\,i\,k$ (fig. 16.) and $l\,m\,n\,o$ be two cylinders of equal length, communicating with each other, and fitted with a piſton-rod $p\,q$, on which are fixed two piſtons $a\,a$ and $b\,b$, whoſe areas are as m and 1. Let the diſtance between the piſtons be preciſely equal to the height of each cylinder, which height we ſhall call h. Let x be the ſpace $g\,b$ or $b\,a$, through which the piſtons have deſcended. Let the upper cylinder communicate with the boiler, and the lower cylinder with the condenſer or vacuum V.

Any perſon in the leaſt converſant in mechanics and pneumatics will clearly ſee that the ſtrain or preſſure on the piſton-rod $p\,q$ is preciſely the ſame with the united energies of the two piſton rods of Mr Hornblower's engine, by which they tend to turn the working beam round its axis.

The baſe of the upper cylinder being 1, and its height h, its capacity or bulk is $1\,h$ or h; and this expreſſes the natural bulk of the ſteam which formerly filled it, and is now expanded into the ſpace $b\,h\,l\,a\,a\,m\,i\,b$. The part $b\,h\,i\,b$ is plainly $=h-x$, and the part $l\,a\,a\,m$ is $=m\,x$. The whole ſpace therefore is $m\,x+h-x$, $=h+m\,x-x$, or $h+\overline{m-1}\,x$. Therefore the denſity of the ſteam between the piſtons is $\dfrac{h}{h+\overline{m-1}\,x}$.

Let p be the downward preſſure of the ſteam from the

(c) This, however, was ſtopped by Watt's patent; and the condenſation muſt be performed as in Newcomen's engine, or at leaſt in the cylinder A.

the boiler on the upper piſton *b b*. This piſton is alſo preſſed up with a force $=p\frac{h}{h+\overline{m-1}\,x}$ by the ſteam between the piſtons. It is therefore, on the whole, preſſed downward with a force $=p\left(1-\frac{h}{h+\overline{m-1}\,x}\right)$. The lower piſton *a a*, having a vacuum below it, is preſſed downwards with a force $=p\frac{m\,h}{h+\overline{m-1}\,x}$. Therefore the whole preſſure on the piſton rod downwards is $=p\left(1+\frac{m\,h}{h+\overline{m-1}\,x}-\frac{h}{h+\overline{m-1}\,x}\right), =p\left(1+\frac{\overline{m-1}\,h}{h+\overline{m-1}\,x}\right), =p+\frac{p\,h\,\overline{m-1}}{h+\overline{m-1}\,x}=p+\frac{p\,h}{\frac{h}{m-1}+x}$.

This then is the momentary preſſure on the piſton rod correſponding to its deſcent x from its higheſt poſition. When the piſtons are in their higheſt poſition, this preſſure is equal to $m\,p$. When they are in their loweſt poſition, it is $=p\frac{2\,m-1}{m}$. Here therefore is an acceſſion of power. In the beginning the preſſure is greater than on a ſingle piſton in the proportion of m to 1; and at the end of the ſtroke, where the preſſure is weakeſt, it is ſtill much greater than the preſſure on a ſingle piſton. Thus, if m be 4, the preſſure at the beginning of the ſtroke is $4\,p$, and at the end it is $\frac{7}{4}\,p$, almoſt double, and in all intermediate poſitions it is greater. It is worth while to obtain the ſum total of all the accumulated preſſures, that we may compare it with the conſtant preſſure on a ſingle piſton.

We may do this by conſidering the momentary preſſure $p+\frac{p\,h}{\frac{h}{m-1}+x}$, as equal to the ordinate GF, H*b*, or M*c*, of a curve F*b c* (fig. 10.), which has for its axis the line GM equal to h the height of our cylinder. Call this ordinate y. We have $y=p+\frac{p\,h}{\frac{h}{m-1}x}$, and $y-p=\frac{p\,h}{\frac{h}{m-1}+x}$. Now it is plain that $\frac{p\,h}{\frac{h}{m-1}+x}$ is the ordinate of an equilateral hyperbola, of which $p\,h$ is the power or rectangle of the ordinate and abſciſs, and of which the abſciſs reckoned from the centre is $\frac{h}{m-1}+x$. Therefore make $\mathrm{GE}=p$, and draw DEA parallel to MG, and make $\mathrm{EA}=\frac{\mathrm{GM}}{m-1}, =\frac{h}{m-1}$. The curve F*b c* is an equilateral hyperbola, having A for its centre and AD for its aſſymptote. Draw the other aſſymptote AB, and its ordinate FB. Since the power of the hyperbola is $=p\,h$, =GEDM (for GE$=p$, and GM$=h$); and ſince all the inſcribed rectangles, ſuch as AEFB, are equal to $p\,h$, it follows that AEFB is equal to GEDM, and that the area ABF*c*DA is equal to the area GF*c*MG, which expreſſes the accumulated preſſure in Hornblower's engine.

We can now compute the accumulated preſſure very eaſily. It is evidently $=p\,h\times\left(1+\mathrm{L}.\frac{\mathrm{AD}}{\mathrm{AE}}\right)$.

82 The accumulated preſſure the ſame with that of Mr Watt's engine.

The intelligent reader cannot but obſerve that this is preciſely the ſame with the accumulated preſſure of a quantity of ſteam admitted in the beginning, and ſtopped in Mr Watt's method, when the piſton has deſcended through the mth part of the cylinder. In conſidering Mr Hornblower's engine, the thing was preſented in ſo different a form that we did not perceive the analogy at firſt, and we were ſurpriſed at the reſult. We could not help even regretting it, becauſe it had the appearance of a new principle and an improvement: and we doubt not but that it appeared ſo to the ingenious author; for we have had ſuch proofs of his liberality of mind as permit us not to ſuppoſe that he ſaw it from the beginning, and availed himſelf of the difficulty of tracing the analogy. And as the thing may miſlead others in the ſame way, we have done a ſervice to the public by ſhowing that this engine, ſo coſtly and ſo difficult in its conſtruction, is no way ſuperior in power to Mr Watt's ſimple method of ſtopping the ſteam. It is even inferior, becauſe there muſt be a condenſation in the communicating paſſages. We may add, that if the condenſation is performed in the cylinder A, which it muſt be unleſs with the permiſſion of Watt and Boulton, the engine cannot be much ſuperior to a common engine; for much of the ſteam from below B will be condenſed between the piſtons by the coldneſs of the cylinder A; and this diminiſhes the downward preſſure on A more than it increaſes the downward preſſure on B. We learn however that, by confining the condenſation to a ſmall *part of the cylinder* A, Mr Hornblower has erected engines clear of Mr Watt's patent, which are conſiderably ſuperior to Newcomen's: ſo has Mr Symington.

83 Still, however, the engine diſcovers ingenuity and ſkill.

We ſaid that there was much ingenuity and real ſkill obſervable in many particulars of this engine. The diſpoſition and connection of the cylinders, and the whole condenſing apparatus, are contrived with peculiar neatneſs. The cocks are very ingenious; they are compoſed of two flat circular plates ground very true to each other, and one of them turns round on a pin through their centres; each is pierced with three ſectoral apertures, exactly correſponding with each other, and occupying a little leſs than one-half of their ſurfaces. By turning the moveable plate ſo that the apertures coincide, a large paſſage is opened for the ſteam; and by turning it ſo that the ſolid of the one covers the aperture of the other, the cock is ſhut. Such regulators are now very common in the caſt iron ſtoves for warming rooms.

Mr Hornblower's contrivance for making the collars for the piſton rods air-tight is alſo uncommonly ingenious. This collar is in fact two, at a ſmall diſtance from each other. A ſmall pipe, branching off from the main ſteam-pipe, communicates with the ſpace between the collars. This ſteam, being a little ſtronger than the preſſure of the atmoſphere, effectually hinders the air from penetrating by the upper collar; and though a little ſteam ſhould get through the lower collar into the cylinder A, it can do no harm. We ſee many caſes in which this pretty contrivance may be of ſignal ſervice.

But

Steam-Engine.

84

The great eſt improvement is the framing of the working beam.

But it is in the framing of the great working beam that Mr Hornblower's ſcientific knowledge is moſt conſpicuous; and we have no heſitation in affirming that it is ſtronger than a beam of the common form, and containing twenty times its quantity of timber. There is hardly a part of it expoſed to a tranverſe ſtrain, if we except the ſtrain of the pump V on the ſtrutt by which it is worked. Every piece is either puſhed or pulled in the direction of its length. We only fear that the bolts which connect the upper beam with the two iron bars under its ends will work looſe in their holes, and tear out the wood which lies between them. We would propoſe to ſubſtitute an iron bar for the whole of this upper beam. This working beam highly deſerves the attention of all carpenters and engineers. We have that opinion of Mr Hornblower's knowledge and talents, that we are confident that he will ſee the fairneſs of our examination of his engine, and we truſt to his candour for an excuſe for our criticiſm.

85

The reciprocating motion of the ſteam-engine is a defect ſtill to be remedied.

The reciprocating motion of the ſteam-engine has always been conſidered as a great defect; for though it be now obviated by connecting it with a fly, yet, unleſs it is an engine of double ſtroke, this fly muſt be an enormous maſs of matter moving with great velocity. Any accident happening to it would produce dreadful effects: A part of the rim detaching itſelf would have the force of a bomb, and no building could withſtand it. Many attempts have been made to produce a circular motion at once by the ſteam. It has been made to blow on the vanes of a wheel of various forms. But the rarity of ſteam is ſuch, that even if none is condenſed by the cold of the vanes, the impulſe is exceedingly feeble, and the expence of ſteam, ſo as to produce any ſerviceable impulſe, is enormous. Mr Watt, among his firſt ſpeculations on the ſteam engine, made ſome attempts of this kind. One in particular was uncommonly ingenious. It conſiſted of a drum turning air-tight within another, with cavities ſo diſpoſed that there was a conſtant and great preſſure urging it in one direction. But no packing of the common kind could preſerve it air-tight with ſufficient mobility. He ſucceeded by immerſing it in mercury, or in an almagam which remained fluid in the heat of boiling water; but the continual trituration ſoon calcined the fluid and rendered it uſeleſs. He then tried Parent's or Dr Barker's mill, incloſing the arms in a metal drum, which was immerſed in cold water. The ſteam ruſhed rapidly along the pipe which was the axis, and it was hoped that a great reaction would have been exerted at the ends of the arms; but it was almoſt nothing. The reaſon ſeems to be, that the greateſt part of the ſteam was condenſed in the cold arms. It was then tried in a drum kept boiling hot; but the impulſe was now very ſmall in compariſon with the expence of ſteam. This muſt be the caſe.

86

Mr Watt's attempts to produce a circular motion by ſteam unſucceſsful.

Mr Watt has deſcribed in his ſpecification to the patent office ſome contrivances for producing a circular motion by the immediate action of the ſteam. Some of theſe produce alternate motions, and are perfectly analogous to his double-ſtroke engine. Others produce a continued motion. But he has not given ſuch a deſcription of his valves for this purpoſe as can enable an engineer to conſtruct one of them. From any gueſs that we can form, we think the machine very imperfect; and we do not find that Mr Watt has ever erected a continuous circular engine. He has doubtleſs found all his attempts inferior to the reciprocating engine with a fly. A very crude ſcheme of this kind may be ſeen in the Tranſactions of the Royal Society of Dublin 1787. But although our attempts have hitherto failed, we hope that the caſe is not yet deſperate: we ſee different principles which have not yet been employed.

87

Still the caſe is not deſperate, for different principles may be employed.

We ſhall conclude our account of this noble engine with obſerving, that Mr Watt's form ſuggeſts the conſtruction of an excellent air-pump. A large veſſel may be made to communicate with a boiler at one ſide, and with the pump-receiver on the other, and alſo with a condenſer. Suppoſe this veſſel of ten times the capacity of the receiver; fill it with ſteam from the boiler, and drive out the air from it; then open its communication with the receiver and the condenſer. This will rarefy the air of the receiver ten times. Repeating the operation will rarefy it 100 times; the third operation will rarefy it 1000 times; the fourth 10,000 times, &c. All this may be done in half a minute.

88

Mr Watt's engine ſuggeſts the conſtruction of an excellent air pump.

Steam-Kitchen.

STEAM-Kitchen. Ever ſince Dr Papin contrived his digeſter (about the year 1690), ſchemes have been propoſed for dreſſing victuals by the ſteam of boiling water. A philoſophical club uſed to dine at Saltero's coffee-houſe, Chelſea, about 40 years ago, and had their victuals dreſſed by hanging them in the boiler of the ſteam-engine which raiſes water for the ſupply of Picadilly and its neighbourhood. They were completely dreſſed, and both expeditiouſly and with high flavour.

A patent was obtained for an apparatus for this purpoſe by a tin-man in London; we think of the name of Tate. They were afterwards made on a much more effective plan by Mr Gregory, an ingenious tradeſman in Edinburgh, and are coming into very general uſe.

It is well known to the philoſopher that the ſteam of boiling water contains a prodigious quantity of heat, which it retains in a latent ſtate ready to be faithfully accounted for, and communicated to any colder body. Every cook knows the great ſcalding power of ſteam, and is diſpoſed to think that it is much hotter than boiling water. This, however, is a miſtake; for it will raiſe the thermometer no higher than the water from which it comes. But we can aſſure the cook, that if he make the ſteam from the ſpout of a tea-kettle paſs through a great body of cold water, it will be condenſed or changed into water; and when one pound of water has in this manner been boiled off, it will have heated the maſs of cold water as much as if we had thrown into it ſeven or eight hundred pounds of boiling hot water.

If, therefore, a boiler be properly fitted up in a furnace, and if the ſteam of the water boiling in it be conveyed by a pipe into a pan containing victuals to be dreſſed, every thing can be cooked that requires no higher degree of heat than that of boiling water: And this will be done without any riſk of ſcorching, or any kind of overheating, which frequently ſpoils our diſhes, and proceeds from the burning heat of air coming to thoſe parts of the pot or pan which is not filled with liquor, and is covered only with a film, which quickly burns and taints the whole diſh. Nor will the cook be ſcorched by the great heat of the open fire that is neceſſary for dreſſing at once a number of diſhes, nor have his perſon and clothes ſoiled by the ſmoke and ſoot unavoidable in the cooking on an open fire. Indeed the whole

whole proceſs is ſo neat, ſo manageable, ſo open to inſpection, and ſo cleanly, that it need neither fatigue nor offend the delicacy of the niceſt lady.

We had great doubts, when we firſt heard of this as a general mode of cookery, as to its economy; we had none as to its efficacy. We thought that the ſteam, and conſequently the fuel expended, muſt be vaſtly greater than by the immediate uſe of an open fire; but we have ſeen a large tavern dinner expeditiouſly dreſſed in this manner, ſeemingly with much leſs fuel than in the common method. The following ſimple narration of facts will ſhow the ſuperiority. In a paper manufactory in this neighbourhood, the vats containing the pulp into which the frames are dipped are about ſix feet diameter, and contain above 200 gallons. This is brought to a proper heat by means of a ſmall cockle or furnace in the middle of the liquor. This is heated by putting in about one hundred weight of coals about eight o'clock in the evening, and continuing this till four next morning, renewing the fuel as it burns away. This method was lately changed for a ſteam heater. A furnace, having a boiler of five or ſix feet diameter and three feet deep, is heated about one o'clock in the morning with two hundred weight of coals, and the water kept in briſk ebullition. Pipes go off from this boiler to ſix vats, ſome of which are at 90 feet diſtance. It is conveyed into a flat box or veſſel in the midſt of the pulp, where it condenſes, imparting its heat to the ſides of the box, and thus heats the ſurrounding pulp. Theſe ſix vats are as completely heated in three hours, expending about three hundred weight of coals, as they were formerly in eight hours, expending near eighteeen hundred weight of coals. Mr Gregory, the inventor of this ſteam-heater, has obtained (in company with Mr Scott, plumber, Edinburgh) a patent for the invention; and we are perſuaded that it will come into very general uſe for many ſimilar purpoſes. The dyers, hatmakers, and many other manufacturers, have occaſion for large vats kept in a continual heat; and there ſeems no way ſo effectual.

Indeed when we reflect ſeriouſly on the ſubject, we ſee that this method has immenſe advantages conſidered merely as a mode of applying heat. The ſteam may be applied to the veſſel containing the victuals in every part of its ſurface: it may even be made to enter the veſſel, and apply itſelf immediately to the piece of meat that is to be dreſſed, and this without any riſk of ſcorching or overdoing.—And it will give out about $\frac{799}{800}$ of the heat which it contains, and will do this only if it be wanted; ſo that no heat whatever is waſted except what is required for heating the apparatus. Experience ſhows that this is a mere trifle in compariſon of what was ſuppoſed neceſſary. But with an open fire we only apply the flame and hot air to the bottom and part of the ſides of our boiling veſſels: and this application is hurried in the extreme; for to make a great heat, we muſt have a great fire, which requires a prodigious and moſt rapid current of air. This air touches our pans but for a moment, imparts to them but a ſmall portion of its heat; and we are perſuaded that three-fourths of the heat is carried up the chimney, and eſcapes in pure waſte, while another great portion beams out into the kitchen to the great annoyance of the ſcorched cook. We think, therefore, that a page or two of this work will not be thrown away in the deſcription of a contrivance by which a ſaving may be made to the entertainer, and the providing the pleaſures of his table prove a leſs fatiguing taſk to this valuable corps of practical chemiſts.

Plate DV. Fig. 1.

Let A (fig. 1.) repreſent a kitchen-boiler, either properly fitted up in a furnace, with its proper fire-place, aſh-pit, and flue, or ſet on a tripod on the open fire, or built up in the general fire-place. The ſteam-pipe BC riſes from the cover of this boiler, and then is led away with a gentle aſcent in any convenient direction. C repreſents the ſection of this conducting ſteam-pipe. Branches are taken off from the ſide at proper diſtances. One of theſe is repreſented at CDE, furniſhed with a cock D, and having a taper nozzle E, fitted by grinding into a conical piece F, which communicates with an upright pipe GH, which is ſoldered to the ſide of the ſtewing veſſel PQRS, communicating with it by the ſhort pipe I. The veſſel is fitted with a cover OT, having a ſtaple handle V. The piece of meat M is laid on a tin-plate grate KL, pierced with holes like a cullender, and ſtanding on three ſhort feet *n n n*.

The ſteam from the boiler comes in by the pipe I, and is condenſed by the meat and by the ſides of the veſſel, communicating to them all its heat. What is not ſo condenſed eſcapes between the veſſel and its cover. The condenſed water lies on the bottom of the veſſel, mixed with a very ſmall quantity of gravy and fatty matter from the victuals. Frequently, inſtead of a cover, another ſtew-veſſel with a cullender bottom is ſet on this one, the bottom of the one fitting the mouth of the other: and *it is obſerved*, that when this is done, the diſh in the under veſſel is more expeditiouſly and better dreſſed, and the upper diſh is more ſlowly, but as completely ſtewed.

This deſcription of one ſtewing veſſel may ſerve to give a notion of the whole; only we muſt obſerve, that when broths, ſoups, and diſhes with made ſauces or containing liquids, are to be dreſſed, they muſt be put into a ſmaller veſſel, which is ſet into the veſſel PQRS, and is ſupported on three ſhort feet, ſo that there may be a ſpace all round it of about an inch or three quarters of an inch. It is obſerved, that diſhes of this kind are not ſo expeditiouſly cooked as on an open fire, but as completely in the end, only requiring to be turned up now and then to mix the ingredients; becauſe as the liquids in the inner veſſel can never come into ebullition, unleſs the ſteam from the boiler be made of a dangerous heat, and every thing be cloſe confined, there cannot be any of that tumbling motion that we obſerve in a boiling pot.

The performance of this apparatus is far beyond any expectation we had formed of it. In one which we examined, ſix pans were ſtewing together by means of a boiler $10\frac{1}{2}$ inches in diameter, ſtanding on a briſk open fire. It boiled very briſkly, and the ſteam puffed frequently through the chinks between the ſtew-pans and their covers. In one of them was a piece of meat conſiderably above 30 pounds weight. This required above four hours ſtewing, and was then very thoroughly and equally cooked; the outſide being no more done than the heart, and it was near two pounds heavier than when put in, and greatly ſwelled. In the mean time, ſeveral diſhes had been dreſſed in the other pans. As far

Steam-Kitchen.

far as we could judge, this cooking did not consume one-third part of the fuel which an open fire would have required for the same effect.

When we consider this apparatus with a little more knowledge of the mode of operation of fire than falls to the share of the cooks (we speak with deference), and consider the very injudicious manner in which the steam is applied, we think that it may be improved so as to surpass any thing that the cook can have a notion of.

When the steam enters the stew-pan, it is condensed on the meat and on the vessel; but we do not want it to be condensed on the vessel. And the surface of the vessel is much greater than that of the meat, and continues much colder; for the meat grows hot, and continues so, while the vessel, made of metal, which is a very perfect conductor of heat, is continually robbed of its heat by the air of the kitchen, and carried off by it. If the meat touch the side of the pan in any part, no steam can be applied to that part of the meat, while it is continually imparting heat to the air by the intermedium of the vessel. Nay, the meat can hardly be dressed unless there be a current of steam through it; and we think this confirmed by what is observed above, that when another stew-pan is set over the first, and thus gives occasion to a current of steam through its cullender bottom to be condensed by its sides and contents, the lower dish is more expeditiously dressed. We imagine, therefore, that not less than half of the steam is wasted on the sides of the different stew-pans. Our first attention is therefore called to this circumstance, and we wish to apply the steam more economically and effectually.

We would therefore construct the steam-kitchen in the following manner:

Fig. 2. We would make a wooden chest (which we shall call the STEW-CHEST) ABCD (fig. 2.). This should be made of deal, in very narrow slips, not exceeding an inch, that it may not shrink. This should be lined with very thin copper, lead, or even strong tinfoil. This will prevent it from becoming a conductor of heat by soaking with steam. For further security it might be set in another chest, with a space of an inch or two all round, and this space filled with a composition of powdered charcoal and clay. This should be made by first making a mixture of fine potter's clay and water about as thick as poor cream: then as much powdered charcoal must be beat up with this as can be made to stick together. When this is rammed in and dry, it may be hot enough on one side to melt glass, and will not discolour white paper on the other.

This chest must have a cover LMNO, also of wood, having holes in it to receive the stew-pans P, Q, R. Between each pan is a wooden partition, covered on both sides with milled lead or tinfoil. The whole top must be covered with very spongy leather or felt, and made very flat. Each stew-pan must have a bearing or shoulder all round it, by which it is supported, resting on the felt, and lying so true and close that no steam can escape. Some of the pans should be simple, like the pan F, for dressing broths and other liquid dishes. Others should be like E and G, having in the bottom a pretty wide hole H, K, which has a pipe in its upper side, rising about an inch or an inch and half into the stew-pan. The meat is laid on a cullender plate, as in the common way; only there must be no holes in the cullender immediately above the pipe.—These stew-pans must be fitted with covers, or they may have others fitted to their mouths, for warming sauces or other dishes, or stewing greens, and many other subordinate purposes for which they may be fitted.

Steam-Kitchen.

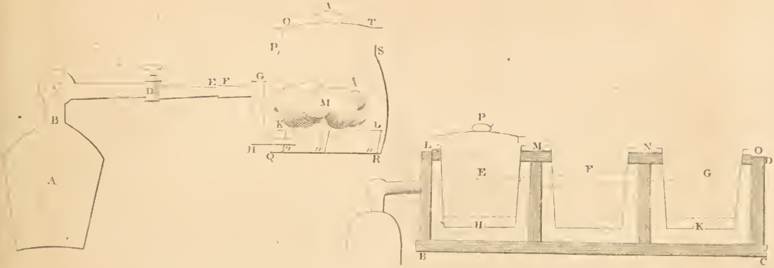
The main-pipe from the boiler must have branches, (each furnished with a cock), which admit the steam into these divisions. At its first entry some will be condensed on the bottom and sides; but we imagine that these will in two minutes be heated so as to condense no more, or almost nothing. The steam will also quickly condense on the stew-pan, and in half a minute make it boiling hot, so that it will condense no more; all the rest will now apply itself to the meat and to the cover. It may perhaps be advisable to allow the cover to condense steam, and even to waste it. This may be promoted by laying on it flannel soaked in water. Our view in this is to create a demand for steam, and thus produce a current through the stew-pan, which will be applied in its passage to the victuals. But we are not certain of the necessity of this. Steam is not like common air of the same temperature, which would glide along the surfaces of bodies, and impart to them a small portion of its heat, and escape with the rest. To produce this effect there *must* be a current; for air hot enough to melt lead, will not boil water, if it be kept stagnant round the vessel. But steam imparts the *whole* of its latent heat to any body colder than boiling water, and goes no farther till this body be made boiling hot. It is a most faithful carrier of heat, and will deliver its whole charge to any body that can take it. Therefore, although there were no partitions in the stew-chest, and the steam were admitted at the end next the boiler, if the pan at the farther end be colder than the rest, it will all go thither; and will, in short, communicate to every thing impartially according to the demand. If any person has not the confidence in the steam which we express, he may still be certain that there must be a prodigious saving of heat by confining the whole in the stew-chest; and he may make the pans with entire bottoms, and admit the steam into them in the common way, by pipes which come through the sides of the chest and then go into the pan. There will be none lost by condensation on the sides of the chest; and the pans will soon be heated up to the boiling temperature; and hardly any of their heat will be wasted, because the air in the chest will be stagnant. The chief reason for recommending our method is the much greater ease with which the stew-pans can be shifted and cleaned. There will be little difference in the performance.

Nay, even the common steam-kitchen may be prodigiously improved by merely wrapping each pan in three or four folds of coarse dry flannel, or making flannel bags of three or four folds fitted to their shape, which can be put on or removed in a minute. It will also greatly conduce to the good performance to wrap the main steam pipe in the same manner in flannel.

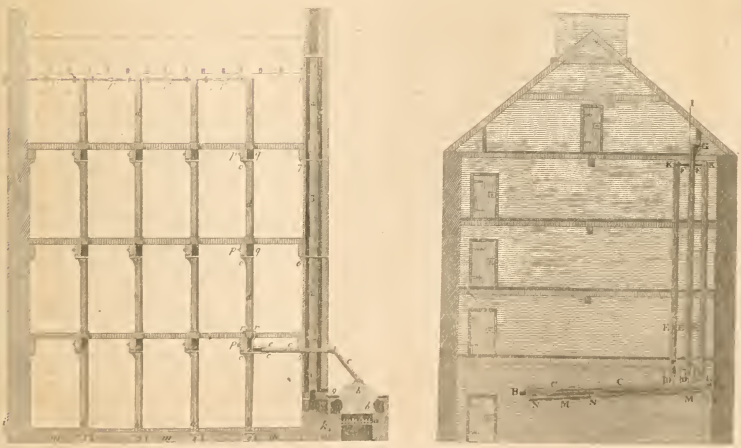
We said that this main-pipe is conducted from the boiler with a gentle ascent. The intention of this is, that the water produced by the unavoidable condensation of the steam may run back into the boiler. But the rapid motion of the steam generally sweeps it up hill, and it runs into the branch-pipes and descends into the stew-pans. Perhaps it would be as well to give the main-

STEAM kitchen

Plate DV.



ROOMS heated by STEAM.



W. Archibald sculp.t

Steam-Kitchen.

main-pipe a declivity the other way, and allow all the water to collect in a hot well at the farther end, by means of a descending pipe, having a loaded valve at the end. This may be so contrived as to be close by the fire, where it would be so warm that it would not check the boiling if again poured into the boiler. But the utmost attention must be paid to cleanliness in the whole of this passage, because this water is boiled again, and its steam passes through the heart of every dish. This circumstance forbids us to return into the boiler what is condensed in the stew-pans. This would mix the tastes and flavours of every dish, and be very disagreeable. All this must remain in the bottom of each stew-pan; for which reason we put in the pipe rising up in the middle of the bottom. It might indeed be allowed to fall down into the stew-chest, and to be collected in a common receptacle, while the fat would float at top, and the clear gravy be obtained below, perhaps fit for many sauces.

The completest method for getting rid of this condensed steam would be to have a small pipe running along the under side of the main conductor, and communicating with it at different places, in a manner similar to the air discharger on the mains of water-pipes. In the paper manufactory mentioned above, each steam-box has a pipe in its bottom, with a float-cock, by which the water is discharged; and the main pipe being of great diameter, and laid with a proper acclivity, the water runs back into the boiler.

But these precautions are of little moment in a steam-kitchen even for a great table; and for the general use of private families, would hurt the apparatus, by making it complex and of nice management. For a small family, the whole apparatus may be set on a table four feet long and two broad, which may be placed on casters, so as to be wheeled out of the way when not in use. If the main conductor be made of wood, or properly cased in flannel, it will condense so little steam that the cooking table may stand in the remotest corner of the kitchen without sensibly impairing its performance; and if the boiler be properly set up in a small furnace, and the flue made so that the flame may be applied to a great part of its surface, we are persuaded that three-fourths of the fuel used in common cookery will be saved. Its only inconvenience seems to be the indispensable necessity of the most anxious cleanliness in the whole apparatus. The most trifling neglect in this will destroy a whole dinner.

We had almost forgotten to observe, that the boiler must be furnished with a funnel for supplying it with water. This should pass through the top, and its pipe reach near to the bottom. It will be proper to have a cock on this funnel. There should also be another pipe in the top of the boiler, having a valve on the top. If this be loaded with a pound on every square inch, and the fire so regulated that steam may be observed to puff sometimes from this valve, we may be certain that it is passing through our dishes with sufficient rapidity; and if we shut the cock on the funnel, and load the valve a little more, we shall cause the steam to blow at the covers of the stew-pans. If one of these be made very tight, and have a hole also furnished with a loaded valve, this pan becomes a digester, and will dissolve bones, and do many things which are impracticable in the ordinary cookery.

Steam.

STEAM applied to Heating Rooms. Steam has been successfully applied as a substitute for open fires in heating manufactories, and promises to be highly beneficial, not only in point of economy in saving fuel, but also in lessening the danger of accidental fire. The following mode of heating a cotton mill by steam was proposed and practised in 1799 by Mr Niel Snodgrass of Paisley. We shall give an account of it in his own words *.

* *Phil. Mag.* xxvii. 174.

Plate DV. Fig. 1

" Fig. 1. presents a view of an inner gable, which is at one extremity of the preparation and spinning rooms of the mill. On the other side of this gable there is a space of 17 feet, enclosed by an outer gable, and containing the water-wheel, the staircase, and small rooms for the accommodation of the work. In this space the furnace and boiler are placed on the ground. The boiler cannot be shown here, as it lies behind the gable exhibited; nor is it of any consequence, as there is nothing peculiar in it. It may be of any convenient form. The feeding apparatus, &c. are in every respect the same as in the boiler of a common steam-engine. A circular copper boiler, two feet diameter by two feet deep, containing 30 gallons of water, with a large copper head as a reservoir for the steam, was found to answer in the present instance. The steam is conveyed from the boiler through the gable, by the copper pipe B, into the tin pipe, C, C. From C it passes into the centres of the perpendicular pipes E, E, E, by the small bent copper tubes D, D, D. The pipes E, E, E, are connected under the garret floor by the tubes F, F, for the more easy circulation of the steam. The middle pipe, E, is carried through the garret floor, and communicates with a lying pipe, 36 feet in length (the end of which is seen at G), for heating the garret. At the further extremity of the pipe G, there is a valve falling inwards to prevent a vacuum being formed on the cooling of the apparatus; the consequence of which would be the crushing of the pipes by the pressure of the atmosphere. Similar valves K, K, are placed near the the top of the perpendicular pipes, E, E; and from the middle one E, the small pipe passes through the roof, and is furnished with a valve at I, opening outwards, to suffer the air to escape while the pipes are filling with steam, or the steam itself to escape when the charge is too high.

" The water condensed in the perpendicular pipes E, E, E, trickles down their sides into the three funnels L, L, L, the necks of which may either pass through or round the pipe C, into the copper tube M, M, which also receives the water condensed in C, C, by means of the short tubes N, N. The pipe C, C, is itself so much inclined as to cause the water to run along it to the tubes N, N, and the pipe G in the garret has an inclination of 18 inches in its length, to bring the water condensed in it back to the middle pipe E. The tube M, M, carries back the water through the gable to the boiler, which stands five feet lower than this tube. It is material to return the water to the boiler, as, being nearly at a boiling heat, a considerable expense of fuel is thereby saved.

" The large pipes are ten inches in diameter, and are made of the second kind of tinned iron plates. The dimensions of the smaller tubes may be seen by their comparative size in the engraving, and perhaps they might be varied without inconvenience.

" The apparatus erected as here described, has been found sufficiently strong, and has required no material repairs re[illegible] ſince the firſt alterations were made. The leading object in the inſtance under conſideration being to ſave fuel, in order to derive as much heat as poſſible from a given quantity of fuel, the flue from the furnace, which heats the boiler, is conveyed into common ſtone pipes placed in the gable. Theſe are erected ſo as to prevent any danger of fire, in the manner ſhown in the engraving, fig. 2. The ſteam with this auxiliary communicates a heat of about 70° to the mill, the rooms of which are 50 feet long, 32½ feet wide, and 8½ feet high, except the lower ſtory and garret; the former of which is 11, and the latter ſeven feet high. The rooms warmed in this manner are much more wholeſome and agreeable than thoſe heated by the beſt conſtructed ſtoves, being perfectly free from vapour or contaminated air.

"The application of the principle to buildings already conſtructed, it is preſumed, will be ſufficiently obvious from the foregoing details. In new manufactories, where the mode of heating may be made a part of the original plan, a more convenient apparatus may be introduced. This will be beſt explained by a deſcription of fig. 2. which gives a ſection of a cotton-mill conſtructed ſo as to apply the ſteam apparatus to a new building.

Fig. 2.

"The furnace for the boiler is ſhown at *a* (fig. 2). The flue of the furnace conveys the ſmoke into the caſt iron ſtove pipes, 1, 2, 3, 4. Theſe pipes are placed in a ſpace in the gable, entirely incloſed with brick, except at the ſmall apertures, 5, 6, 7, 8. A current of air is admitted below at 9, and thrown into the rooms by thoſe openings, after being heated by contact with the pipes. This part of the plan is adopted with a view to prevent, as much as poſſible, any of the heat, produced by the fuel uſed, from being thrown away. It may be omitted where any danger of fire is apprehended from it, and the ſmoke may be carried off in any way that is conſidered abſolutely ſecure. So far, however, as appears from experience, there ſeems to be little or no danger of fire from a ſtove of this conſtruction. The greateſt inconvenience of a common ſtove is, that the cockle or metal furnace is liable to crack from the intenſity of the heat. By the continuity of the metal from the fireplace, an intenſe heat is alſo conducted along the pipes, which expoſes them to the ſame accident. Here the ſmoke being previouſly conveyed through a brick flue, can never communicate to the pipes a degree of heat ſufficient to crack them. In like manner the pipes, having no communication with the rooms but by the ſmall apertures, cannot come in contact with any combuſtible ſubſtance; and from being ſurrounded with air, which is conſtantly changing, can impart only a very moderate degree of heat to the walls. The iron ſupporters of the pipes may be imbedded in ſome ſubſtance which is a bad conductor of heat, as furnace aſhes and lime, &c. The emiſſion of heated air into the rooms may be regulated by valves. As the pipes are not expoſed to cracking, there is no riſk of their throwing ſmoke or vapour into the rooms.

"The boiler *b b*, is ſix feet long, three and a half broad, and three feet deep. As there is nothing peculiar in the feeding apparatus, it is omitted. The boiler may be placed in any convenient ſituation. Where a ſteam engine is uſed for other purpoſes, the ſteam may be taken from its boiler. The pipe *c, c*, conveys the ſteam from the boiler to the firſt perpendicular pipe *d, d, d, d*. There is an expanding joint at *e*, ſtuffed, to make it ſteam-tight. The ſteam aſcending in the firſt pipe *d, d, d*, enters the horizontal pipe *f, f, f, f*, (which is ſlightly inclined) expelling the air, which partly eſcapes by the valve *g*, and is partly forced into the other pipes. The valve *g* being conſiderably loaded, forces the accumulating ſteam down into the reſt of the pipes *d, d, d*. The air in theſe pipes recedes before the ſteam, and is forced through the tubes *h, h, h*, into the pipe *m, m, m*, whence it eſcapes at the valve *i*, and the ſyphon *k*. The water, condenſed in the whole of the pipes, paſſes alſo through the tubes *h, h, h, h*, into the pipe *m, m, m*, which has ſuch a declivity as to diſcharge the water at the ſyphon *k*, into the hot well *n*, whence it is pumped back into the boiler.

"The whole of the pipes are of caſt iron, except *m, m, m*, which is of copper. The perpendicular pipes ſerve as pillars for ſupporting the beams of the houſe, by means of the projecting pieces *o, o, o*, which may be raiſed or lowered at pleaſure by the wedges *p, p, p*. The pipes are ſunk in the beams about an inch, and are made faſt to them by the iron ſtraps *q, q*. Thoſe in the lower ſtory reſt on the ſtones *s, s, s, s*, and are made tight at the junction with ſtuffing. The pipe in each ſtory ſupports the one in the ſtory above by a ſtuffed joint as ſhown at *r*. The pipes in the lower ſtory are ſeven inches in diameter; thoſe in the higher ſix inches; thoſe in the other two are of intermediate diameters. The thickneſs of the metal is three-eighths of an inch. The lower pipes are made larger than the upper, in order to expoſe a greater heated ſurface in the lower rooms, becauſe the ſteam being thrown from above into all the pipes, except the firſt, would otherwiſe become incapable of imparting an equal heat as it deſcends. There is no neceſſity for valves opening inwards in this apparatus, the pipes being ſtrong enough to reſiſt the preſſure of the atmoſphere.

"The cotton mill is 60 feet long, 33 wide, and four ſtories high, the upper being a garret ſtory. In the engraving, five parts out of nine in the length of the building are only ſhown. The apparatus will heat the rooms to 85° in the coldeſt ſeaſon. It is evident that, by increaſing the ſize, or the number of the pipes, and the ſupply of ſteam, any degree of heat up to 212° may be eaſily produced. It may even be carried beyond that point by an apparatus ſtrong enough to compreſs the ſteam: this, however, can ſeldom be wanted. At firſt it was objected to this conſtruction, that the expanſion of the pipes, when heated, might damage the building: but experience has proved, that the expanſion occaſioned by the heat of ſteam is quite inſenſible."

Steam has alſo been advantageouſly employed in drying muſlin goods, when the ſtate of the weather interrupts this proceſs out of doors. This application of ſteam, we underſtand, was the invention of an ingenious mechanic in Paiſley, who never derived the ſmalleſt benefit from the diſcovery. It was adopted immediately by ſome bleachers in the neighbourhood, and has now come into very general uſe. The ſteam is introduced into cylinders of tin plate, and the goods to be dried are wrapped round the cylinders which communicate to them a heat equal at leaſt to the temperature of boiling water, and in this way the proceſs of drying is expeditiouſly accompliſhed.

STEATITES or *Soap-earth*, a ſpecies of mineral belonging

Steatites belonging to the magnesian genus. See MINERALOGY *Index*.

STEATOMA, a kind of encysted tumor, consisting of a matter like suet or lard, soft, without pain, and without discolouring the skin.

STEEL, iron united with carbone, from which it possesses properties distinct from those of iron, and which render it of superior value. From its higher degree of hardness it admits a finer polish and assumes a brighter colour. When tempered, it possesses a higher degree of elasticity, and is also more sonorous. It is more weakly attracted by the loadstone, it receives more slowly the magnetic power, but it preserves it longer. When exposed to a moist air, it does not contract rust so easily as iron. See IRON, CHEMISTRY *Index*.

STEEL-Bow Tenants. See TENURE.

STEEL-Yard, is one of the most ancient presents which science has made to society; and though long in desuetude in this country, is in most nations of the world the only instrument for ascertaining the weight of bodies. What is translated *balance* in the Pentateuch, is in fact steelyard, being the word used by the Arabs to this day for their instrument, which is a steelyard. It is in common use in all the Asiatic nations. It was the *statera* of the Greeks and Romans, and seems to have been more confided in by them than the balance; for which reason it was used by the goldsmiths, while the balance was the instrument of the people.—*Non aurificis statera sed populari trutina examinare*. Cic. de Orat. 238.

The steelyard is a lever of unequal arms, and, in its most perfect form, is constructed much like a common balance. It hangs in the sheers E (fig. 1,) resting on the nail C, and the scale L for holding the goods hangs by a nail D on the short arm BC. The counter weight P hangs by a ring of tempered steel, made sharp in the inside, that it may bear by an edge on the long arm CA of the steelyard. The under edge of the centre nail C, and the upper edge of the nail D, are in the straight line formed by the upper edge of the long arm. Thus the three points of suspension are in one straight line. The needle or index of the steelyard is perpendicular to the line of the arms, and plays between the sheers. The short arm may be made so massive, that, together with the scale, it will balance the long arm unloaded. When no goods are in the scale, and the counter weight with its hook are removed, the steelyard acquires a horizontal position, in consequence of its centre of gravity being below the axis of suspension. The rules for its accurate construction are the same as for a common balance.

Plate DVI. Fig. 1.

The instrument indicates different weights in the following manner: The distance CD of the two nails is considered as an unit, and the long arm is divided into a number of parts equal to it; and these are subdivided as low as is thought proper; or in general, the long arm is made a scale of equal parts, commencing at the edge of the nail C; and the short arm contains some determined number of these equal parts. Suppose, then, that a weight A of 10 pounds is put into the scale L. The counterpoise P must be of such a weight, that, when hanging at the division 10, it shall balance this weight A. Now let any unknown weight W be put into the scale. Slide the hook of the counterpoise along the long arm till it balances this weight. Suppose it then hanging at the division 38. We conclude that there is 38 pounds in the scale. This we do on the authority of the fundamental property of the lever, that forces acting on it, and balancing each other, are in the inverse proportion of the distances from the fulcrum to their lines of direction. Whatever weight the counterpoise is, it is to A as CD to 10, and it is to the weight W as CD to 38; therefore A is to the weight W as 10 to 38, and W is 38 pounds: and thus the weight in the scale will always be indicated by the division at which it is balanced by the counterpoise.

Our well-informed readers know that this fundamental property of the lever was discovered by the renowned Archimedes, or at least first demonstrated by him; and that his demonstration, besides the defect of being applicable only to commensurable lengths of the arms, has been thought by metaphysicians of the first note to proceed on a postulate which seems equally to need a demonstration. It has accordingly employed the utmost refinement of the first mathematicians of Europe to furnish a demonstration free from objection. Mr D'Alembert has given two, remarkable for their ingenuity and subtlety; Foncenex has done the same; and Professor Hamilton of Trinity-college, Dublin, has given one which is thought the least exceptionable. But critics have even objected to this, as depending on a postulate which should have been demonstrated.

The following demonstration by Mr Vince, we think unexceptionable, and of such simplicity that it is astonishing that it has not occurred to any person who thinks on the subject. Fig. 2.

Let AE (fig. 2.) be a mathematical lever, or inflexible straight line, resting on the prop A, and supported at D by a force acting upwards. Let two equal weights b and d be hung on at B and D, equidistant from A and E. Pressures are now exerted at A and E; and because every circumstance of weight and distance is the same, the pressure at E, arising from the action of the weight b on the point B, must be the same with the pressure at A, arising from the action of the weight d on the point D; and the pressure at E, occasioned by the weight d, must be the same with the pressure at A, occasioned by the weight b. This must be the case wherever the weights are hung, provided that the distances AB and DE are equal. Moreover, the sum of the pressures at A and E is unquestionably equal to the sum of the weights, because the weights are supported solely at A and E. Let the two weights be hung on at C the middle point; the pressure at E is still the same. Therefore, in general, the pressure excited at the point E, by two equal weights hanging at any points B and D, is the same as if they were hung on at the middle point between them: but the pressure excited at E is a just measure of the effort or energy of the weights b and d to urge the lever round the point A. It is, at least, a measure of the opposite force which must be applied at E to sustain or balance this pressure. A very fastidious metaphysician may still say, that the demonstration is limited to a point E, whose distance from A is twice AC, or $= AB + AD$. But it extends to any other point on the authority of a postulate which cannot be refused, viz. that in whatever proportion the pressure at E is augmented or diminished, the pressure at this other point must augment or diminish in the same proportion. This being proved, the general theorem may be demonstrated

Steel-yard. ted in all proportions of diftance, in the manner of Archimedes, at once the moft fimple, perfpicuous, and elegant of all.

We cannot help obferving, that all this difficulty (and it is a real one to the philofopher who aims at rendering mechanics a demonftrative fcience) has arifen from an improper fearch after fimplicity. Had Archimedes taken a lever as it really exifts in nature, and confidered it as *material*, confifting of atoms united by cohefion; and had he traced the intermediate preffures by whofe means the two external weights are put in oppofition to each other, or rather to the fupport given to the fulcrum; all difficulty would have vanifhed. (See what is faid on this fubject in the article *STRENGTH of Timber*, &c.

The quantity of goods which may be weighed by this inftrument depends on the weight of the counterpoife, and on the diftance CD from the fulcrum at which the goods are fufpended. A double counterpoife hanging at the fame divifion will balance or indicate a double quantity of goods hanging at D; and any counterpoife will balance and indicate a double quantity of goods, if the diftance CD be reduced to one half. And it fometimes occurs that fteelyards are fo conftructed that they have two or more points of fufpenfion D, to which the fcale may occafionally be attached. It is evident, that in this cafe the value or indication of the divifions of the long arm will be different, according to the point from which the fcale is fufpended. The fame divifion which would indicate 20 pounds when CD is three inches, will indicate 30 pounds when it is two inches. As it would expofe to chance of miftakes, and be otherwife troublefome to make this reduction, it is ufual to make as many divided fcales on the long arm as there are points of fufpenfion D on the fhort arm; and each fcale having its own numbers, all trouble and all chance of miftake is avoided.

But the range of this inftrument is not altogether at the pleafure of the maker. Befides the inability of a flender beam to carry a great load, the divifions of the fcale anfwering to pounds or half-pounds become very minute when the diftance CD is very fhort; and the balance becomes lefs delicate, that is, lefs fenfibly affected by fmall differences of weight. This is becaufe in fuch cafes the thicknefs which it is neceffary to give the edges of the nails does then bear a fenfible proportion to the diftance CD between them; fo that when the balance inclines to one fide, that arm is fenfibly fhortened, and therefore the energy of the preponderating weight is leffened.

We have hitherto fuppofed the fteelyard to be in equilibrio when not loaded. But this is not neceffary, nor is it ufual in thofe which are commonly made. The long arm commonly preponderates confiderably. This makes no difference, except in the beginning of the fcale. The preponderancy of the long arm is equivalent to fome goods already in the fcale, fuppofe four pounds. Therefore when there are really 10 pounds in the fcale, the counterpoife will balance it when hanging at the divifion 6. This divifion is therefore reckoned 10, and the reft of the divifions are numbered accordingly.

A fcientific examination of the fteelyard will convince us that it is inferior to the balance of equal arms in point of fenfibility: But it is extremely compendious and convenient; and when accurately made and attentively ufed, it is abundantly exact for moft commercial purpofes. We have feen one at Leipzig which has been in ufe fince the year 1718, which is very fenfible to a difference of one pound, when loaded with nearly three tons on the fhort arm; and we faw a waggon loaded with more than two tons weighed by it in about fix minutes.

The fteelyard in common ufe in the different countries of Europe is of a conftruction ftill fimpler than what we have defcribed. It confifts of a batten of hard wood, having a heavy lump A (fig. 3.) at one end, and a fwivel-hook B at the other. The goods to be weighed are fufpended on the hook, and the whole is carried in a loop of whip-cord C, in which it is flid backward and forward, till the goods are balanced by the weight of the other end. The weight of the goods is eftimated by the place of the loop on a fcale of divifions in harmonic progreffion. They are marked (we prefume) by trial with known weights. Fig. 3.

The chief ufe that is now made of the fteelyard in thefe kingdoms is for the weighing of loaded waggons and carts. For this it is extremely convenient, and more than fufficiently exact for the purpofe in view. We fhall defcribe one or two of the moft remarkable; and we fhall begin with that at Leipzig already mentioned.

This fteelyard is reprefented in fig. 4. as run out, Fig. 4. and juft about to be hooked for lifting up the load. The fteelyard itfelf is OPQ, and is about 12 feet long. The fhort arm PQ has two points of fufpenfion *c* and *b*; and the ftirrup which carries the chains for holding the load is made with a double hook, inftead of a double eye, that it may be eafily removed from the one pin to the other. For this purpofe the two hooks are connected above an hafp or ftaple, which goes over the arm of the fteelyard like an arch. This is reprefented in the little figure above the fteelyard. The fufpenfion is fhifted when the fteelyard is run in under cover, by hooking to this ftaple the running block of a fmall tackle which hangs in the door through which the fteelyard is run out and in. This operation is eafy, but neceffary, becaufe the ftirrup, chains, and the ftage on which the load is placed, weigh fome hundreds.

The outer pin *b* is 14 inches, and the inner one *c* is feven inches, diftant from the great nail which refts in the fheers. The other arm is about $10\frac{1}{2}$ feet long, formed with an obtufe edge above. On the inclined plane on each fide of the ridge is drawn the fcale of weights adapted to the inner pin *c*. The fcales correfponding to the outer pin *b* are drawn on the upright fides. The counterpoife flides along this arm, hanging from a faddle-piece made of brafs, that it may not contract ruft. The motion is made eafy by means of rollers. This is neceffary, becaufe the counterpoife is greatly above a hundred weight. This faddle-piece has like two laps on each fide, on which are engraved vernier fcales, which divide their refpective fcales on the arm to quarters of a pound. Above the faddle is an arch, from the fummit of which hangs a little plummet, which fhows the equilibrium of the fteelyard to the weigher, becaufe the fheers are four feet out of the houfe, and he cannot fee their coincidence with the needle of the fteelyard. Laftly, near the end of the long arm are

Fig. 4.

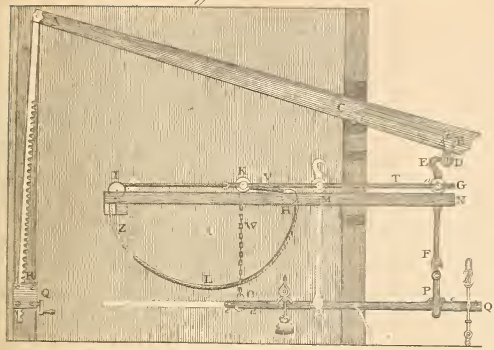


Fig. 2.

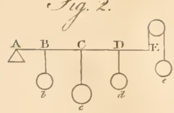

Fig. 1.

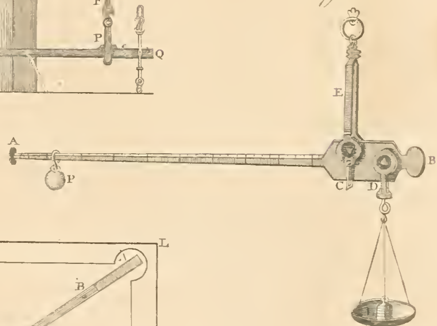

Fig. 5.

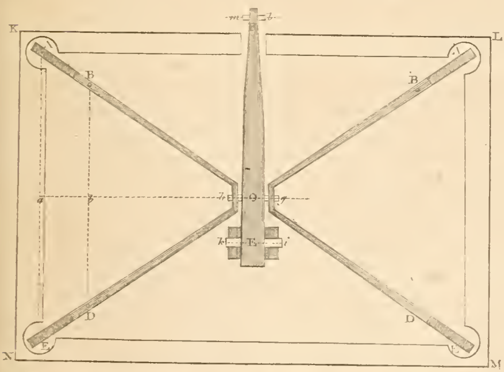

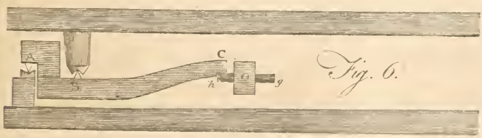

Fig. 6.

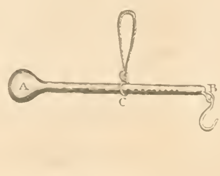
Fig. 3.



Steel-yard. are two pins d and e, for fufpending occafionally two eke weights for continuing the fcale. Thefe are kept hanging on adjoining hooks, ready to be lifted on by a little tackle, which is alfo hooked immediately above the pins d and e.

The fcales of weights are laid down on the arm as follows. Let the eke-weights appropriated to the pins d and e be called D and E, and call the counterpoife C. Although the ftirrup with its chains and ftage weigh fome hundreds, yet the length and fize of the arm OP gives it a preponderancy of 300 pounds. Here, then, the fcale of weights muft commence. The counterpoife weighs about 125 pounds. Therefore,

1. When the load hangs by the pin b, 14 inches from the centre, the diftance from one hundred to another on the fcale is about 11 inches, and the firft fcale (on the fide of the arm) reaches from 300 to 1200. In order to repeat or continue this, the eke-weight E is hung on the pin e, and the counterpoife C is brought back to the mark 300; and the two together balance 1100 pounds hanging at b. Therefore a fecond fcale is begun on the fide of the arm, and continued as far out as the firft, and therefore its extremity marks 2000; that is, the counterpoife C at 2000 and the eke-weight E at e balance 2000 hanging at b.

2. To continue the fcale beyond 2000, the load muft be hung on the inner pin c. The eke-weight E is taken off, and the eke-weight D is hung on its pin d. The general counterpoife being now brought clofe to the fheers, it, together with the weight D at d, balance 2000 pounds hanging at c. A fcale is therefore begun on one of the inclined planes a-top, and continued out to 4000, which falls very near to the pin d, each hundred pounds occupying about five inches on the arm. To complete the fcale, hang on the eke-weight E on its pin e, and bring back the counterpoife to the fheers, and the three together balance 3800 hanging at c. Therefore when the counterpoife is now flid out to 4000, it muft complete the balance with 5800 hanging at c.

It required a little confideration to find out what proportion of the three weights C, D, and E, would make the repetitions of the fcale extend as far as poffible, having very little of it expreffed twice, or upon two fcales, as is the cafe here. We fee that the fpace correfponding to a fingle pound is a very fenfible quantity on both fcales, being one-ninth of an inch on the firft two fcales, and one-twentieth on the laft two.

This very ponderous machine, with its maffy weights, cannot be eafily managed without fome affiftance from mechanics. It is extremely proper to have it fufceptible of motion out and in, that it may be protected from the weather, which would foon deftroy it by ruft. The contrivance here is very effectual, and abundantly fimple.

When the fteelyard is not in ufe, it is fupported at one end by the iron rod F, into which the upper end of the fheers is hooked. The upper end of this rod has a ftrong hook E, and a little below at a it is pierced with a hole, in which is a very ftrong bolt or pin of tempered fteel, having a roller on each end clofe to the rod on each fide. Thefe rollers reft on two joifts, one of which is reprefented by MN, which traverfe the building, with juft room enough between them to allow the rod F to hang freely down. The other end O of the fteelyard refts in the bight of a large flat hook at the end of a chain W, which hangs down between Steel-yard. the joifts, and is fupported on them by a frame with rollers H. This is connected with the rollers at G, which carry the fheers by means of two iron-rods, of which one only can be feen. Thefe connect the two fets of rollers in fuch a manner that they muft always move together, and keep their diftance invariable. This motion is produced by means of an endlefs rope HI ZLKVH paffing over the pulleys I and K, which turn between the joifts, and hanging down in a bight between them. It is evident that by pulling on the part LZ we pull the frame of rollers in the direction GH, and thus bring the whole into the houfe in the pofition marked by the dotted figure. It is alfo plain, that by pulling on the part LK we force the roller frame and the whole apparatus out again.

It remains to fhow how the load is raifed from the ground and weighed. When the fteelyard is run out for ufe, the upper hook E juft enters into the ring D, which hangs from the end of the great oaken lever BCA about 22 feet long, turning on gudgeons at C about 5 feet from this end. From the other end A defcends a long iron-rod SR, which has one fide formed into a toothed rack that is acted on by a frame of wheel-work turned by an endlefs fcrew and winch Q. Therefore when the hook E is well engaged in the ring D, a man turns the winch, and thus brings down the end A of the great lever, and raifes the load two or three inches from the ground. Every thing is now at liberty, and the weigher now manages his weights on the arm of the fteelyard till he has made an equilibrium.

We need not defcribe the operation of letting down the load, difengaging the fteelyard from the great lever, and bringing it again under cover. The whole of this fervice is performed by two men, and may be done in fucceffion by one, and is over in five or fix minutes.

The moft compendious and economical machine of this kind that we have feen is one, firft ufed (we have heard) for weighing the riders of race-horfes, and afterwards applied to the more reputable fervice of weighing loaded carriages.

Fig. 5. Fig. 5. is a plan of the machine. KLMN is the plan of a rectangular box, which has a platform lid or cover, of fize fufficient for placing the wheels of a cart or waggon. The box is about a foot deep, and is funk into the ground till the platform cover is even with the furface. In the middle of the box is an iron lever fupported on the fulcrum pin ik, formed like the nail of a balance, which refts with its edge on arches of hardened fteel firmly faftened to the bottom of the box. This lever goes through one fide of the box, and is furnifhed at its extremity with a hard fteel pin lm, alfo formed to an edge below. In the very middle of the box it is croffed by a third nail of hardened fteel gh, alfo formed to an edge, but on the upper fide. Thefe three edges are in one horizontal plane, as in a well made balance.

In the four corners A, A′, E′, E, of the box are firmly fixed four blocks of tempered fteel, having their upper furfaces formed into fpherical cavities, well polifhed and hard tempered. ABCDE reprefents the upper edge of an iron bar of confiderable ftrength, which refts on the cavities of the fteel blocks in A and E, by means of of two hard steel studs projecting from its under edge, and formed into obtuse-angled points or cones. These points are in a straight line parallel to the side KN of the box. The middle part C of this crooked bar is faced with hard-tempered steel below, and is there formed into an edge parallel to AE and KN, by which it rests on the upper edge of the steel pin $g\,h$ which is in the lever. In a line parallel to AE, and on the upper side of the crooked bar ACE, are fixed two studs or points of hardened steel B and D projecting upwards above half an inch. The platform-cover has four short feet like a stool, terminated by hard steel studs, which are shaped into spherical cavities and well polished. With these it rests on the four steel points B, B′, D′, D. The bar ACE is kneed in such a manner vertically, that the points A, B, D, E and the edge C are all in a horizontal plane. These particulars will be better understood by looking at the elevation in fig. 6. What has been said of the bar ACE must be understood as also said of the bar A′ C′ E′.

Draw through the centre of the box the line $a\,b\,c$ perpendicular to the line AE, BD. It is evident that the bar ACE is equivalent to a lever $a\,b\,c$, having the fulcrum or axis AE resting with its extremity C on the pin $h\,g$ and loaded at b. It is also evident that a C is to $a\,b$ as the load on this lever to the pressure which it exerts on the pin $g\,h$, and that the same proportion subsists between the whole load on the platform and the pressure which it exerts on the pin $g\,h$. It will also appear on an attentive consideration, that this proportion is nowise deranged in whatever manner the load is placed on the platform. If very unequably, the two ends of the pin $g\,h$ may be unequally pressed, and the lever wrenched and strained a little; but the total pressure is not changed.

If there be now placed a balance or steelyard at the side LK, in such a manner that one end of it may be directly above the pin $l\,m$ in the end of the lever EOF, they may be connected by a wire or slender rod, and a weight on the other arm of the balance or steelyard may be put in equilibrio with any load that can be laid on the platform. A small counterpoise being first hung on to balance the apparatus when unloaded, any additional weight will measure the load really laid on the platform. If $a\,b$ be to $a\,c$ as 1 to 8, and EO to EF, also as 1 to 8, and if a common balance be used above, 64 pounds on the platform will be balanced by one pound in the scale, and every pound will be balanced by $\frac{1}{4}$th of an ounce. This would be a very convenient partition for most purposes, as it would enable us to use a common balance and common weights to complete the machine: Or it may be made with a balance of unequal arms, or with a steelyard.

Some have thought to improve this instrument by using edges like those of the nails of a balance, instead of points. But unless made with uncommon accuracy, they will render the balance very dull. The small deviation of the two edges A and E, or of B and D, from perfect parallelism to KN, is equivalent to a broad surface equal to the whole deviation. We imagine that, with no extraordinary care, the machine may be made to weigh within $\frac{1}{1000}$ of the truth, which is exact enough for any purpose in commerce.

It is necessary that the points be attached to the bars. Some have put the points at A and E in the blocks of steel fastened to the bottom, because the cavities in these collect water or dirt, which soon destroyed the instrument with rust. But this occasions a change of proportion in the first lever by any shifting of the crooked bars; and this will frequently happen when the wheels of a loaded cart are pushed on the platform. The cavity in the steel stud should have a little rim round it, and it should be kept full of oil. In a nice machine a quarter of an inch of quicksilver would effectually prevent all these inconveniences.

The simplest and most economical form of this machine is to have no balance or second steelyard; but to make the first steelyard EOF a lever of the first kind, viz. having the fulcrum between O and F, and allow it to project far beyond the box. The long or outward arm of this lever is then divided into a scale of weights, commencing at the side of the box. A counterpoise must be chosen, such as will, when at the beginning of the scale, balance the smallest load that will probably be examined. It will be convenient to carry on this scale by means of eke-weights hung on at the *extremity* of the lever, and to use but one moveable weight. By this method the divisions of the scale will always have one value. The best arrangement is as follows: Place the mark O at the beginning of the scale, and let it extend only to 100, if for pounds; or to 112, if for cwts.; or to 10, if for stones; and let the eke-weights be numbered 1, 2, 3, &c. Let the lowest weight be marked on the beam. This is always to be added to the weight shown by the operation. Let the eke-weights stand at the end of the beam, and let the general counterpoise always hang at O. When the cart is put on the platform, the end of the beam tilts up. Hang on the heaviest eke-weight that is not sufficient to press it down. Now complete the balance by sliding out the counterpoise. Suppose the constant load to be 312lb. and that the counterpoise stands at 86, and that the eke-weight is 9; we have the load $=986+312,=1298$lbs.

STEELE, Sir Richard, was born about the year 1676 in Dublin; in which kingdom one branch of the family was possessed of a considerable estate in the county of Wexford. His father, a counsellor at law in Dublin, was private secretary to James duke of Ormond; but he was of English extraction: and his son, while very young, being carried to London, he put him to school at the Charter-house, whence he was removed to Merton College in Oxford. Our author left the university, which he did without taking any degree, in the full resolution to enter into the army. This step was highly displeasing to his friends; but the ardour of his passion for a military life rendered him deaf to any other proposal. Not being able to procure a better station, he entered as a private gentleman in the horse guards, notwithstanding he thereby lost the succession to his Irish estate. However, as he had a flow of good nature, a generous openness and frankness of spirit, and a sparkling vivacity of wit, these qualities rendered him the delight of the soldiery, and procured him an ensign's commission in the guards. In the mean time, as he had made choice of a profession which set him free from all the ordinary restraints in youth, he spared not to indulge his inclinations in the wildest excesses. Yet his gaieties and revels did not pass without some cool hours of reflection; it was in these that he drew up his little treatise intitled

The

Steele. *The Chriſtian Hero*, with a deſign, if we may believe himſelf, to be a check upon his paſſions. For this purpoſe it had lain ſome time by him, when he printed it in 1701, with a dedication to Lord Cutts, who had not only appointed him his private ſecretary, but procured for him a company in Lord Lucas's regiment of Fuſileers.

The ſame year he brought out his comedy called *The Funeral*, or *Grief à la Mode*. This play procured him the regard of King William, who reſolved to give him ſome eſſential marks of his favour; and though, upon that prince's death, his hopes were diſappointed, yet, in the beginning of Queen Anne's reign, he was appointed to the profitabte place of gazetteer. He owed this poſt to the friendſhip of Lord Halifax and the earl of Sunderland, to whom he had been recommended by his ſchoolfellow Mr Addiſon. That gentleman alſo lent him an helping hand in promoting the comedy called *The Tender Huſband*, which was acted in 1704 with great ſucceſs. But his next play, The Lying Lover, had a very different fate. Upon this rebuff from the ſtage, he turned the ſame humorous current into another channel; and early in the year 1709, he began to publiſh the Tatler: which admirable paper was undertaken in concert with Dr Swift. His reputation was perfectly eſtabliſhed by this work; and, during the courſe of it, he was made a commiſſioner of the ſtamp-duties in 1710. Upon the change of the miniſtry the ſame year, he joined the duke of Marlborough, who had ſeveral years entertained a friendſhip for him; and upon his Grace's diſmiſſion from all employments in 1711, Mr Steele addreſſed a letter of thanks to him for the ſervices which he had done to his country. However, as our author ſtill continued to hold his place in the ſtamp-office under the new adminiſtration, he wiſely declined the diſcuſſion of political ſubjects; and, adhering more cloſely to Mr Addiſon, he dropt the Tatler, and afterwards, by the aſſiſtance chiefly of that ſteady friend, he carried on the ſame plan, much improved, under the title of *The Spectator*. The ſucceſs of this paper was equal to that of the former; which encouraged him, before the cloſe of it, to proceed upon the ſame deſign in the character of the Guardian. This was opened in the beginning of the year 1713, and was laid down in October the ſame year. But in the courſe of it his thoughts took a ſtronger turn to politics: he engaged with great warmth againſt the miniſtry; and being determined to proſecute his views that way by procuring a ſeat in the houſe of commons, he immediately removed all obſtacles thereto. For that purpoſe he took care to prevent a forcible diſmiſſion from his poſt in the ſtamp-office, by a timely reſignation of it to the earl of Oxford; and at the ſame time gave up a penſion, which had been till this time paid him by the queen as a ſervant to the late Prince George of Denmark. This done, he wrote the famous Guardian upon the demolition of Dunkirk, which was publiſhed Auguſt 7. 1713; and the parliament being diſſolved next day, the Guardian was ſoon followed by ſeveral other warm political tracts againſt the adminiſtration. Upon the meeting of the new parliament, Mr Steele having been returned a member for the borough of Stockbridge in Hampſhire, took his ſeat accordingly in the houſe of commons; but was expelled thence in a few days after, for writing the cloſe of the paper called the *Engliſhman*, and one of his political pieces intitled the *Criſis*. Preſently after his expulſion, he publiſhed propoſals for writing the hiſtory of the duke of Marlborough; at the ſame time he alſo wrote the *Spinſter*; and, in oppoſition to the *Examiner*, he ſet up a paper called the *Reader*, and continued publiſhing ſeveral other things in the ſame ſpirit till the death of the queen. Immediately after which, as a reward for theſe ſervices, he was taken into favour by her ſucceſſor to the throne, King George I. He was appointed ſurveyor of the royal ſtables at Hampton-Court, governor of the royal company of comedians, put into the commiſſion of the peace for the county of Middleſex, and in 1715 received the honour of knighthood. In the firſt parliament of that king, he was choſen member for Boroughbridge in Yorkſhire; and, after the ſuppreſſion of the rebellion in the north, was appointed one of the commiſſioners of the forfeited eſtates in Scotland. In 1718, he buried his ſecond wife, who had brought him a handſome fortune and a good eſtate in Wales; but neither this, nor the ample additions lately made to his income, were ſufficient to anſwer his demands. The thoughtleſs vivacity of his ſpirit often reduced him to little ſhifts of wit for its ſupport; and the project of the fiſh pool this year owed its birth chiefly to the projector's neceſſities. This veſſel was intended to carry fiſh alive, and without waſting, to any part of the kingdom: but notwithſtanding all his towering hopes, the ſcheme proved very ruinous to him; for after he had been at an immenſe expence in contriving and building his veſſel, beſides the charge of the patent, which he had procured, it turned out upon trial to be a mere project. His plan was to bring ſalmon alive from the coaſt of Ireland; but theſe fiſh, though ſupplied by this contrivance with a continual ſtream of water while at ſea, yet uneaſy at their confinement, ſhattered themſelves to pieces againſt the ſides of the pool; ſo that when they were brought to market they were worth very little.

The following year he oppoſed the remarkable peerage bill in the houſe of commons; and, during the courſe of this oppoſition to the court, his licence for acting plays was revoked, and his patent rendered ineffectual, at the inſtance of the lord chamberlain. He did his utmoſt to prevent ſo great a loſs; and finding every direct avenue of approach to his royal maſter effectually barred againſt him by his powerful adverſary, he had recourſe to the method of applying to the public, in hopes that his complaints would reach the ear of his ſovereign, though in an indirect courſe, by that canal. In this ſpirit he formed the plan of a periodical paper, to be publiſhed twice a week, under the title of the *Theatre*; the firſt number of which came out on the 2d of January 1719-20. In the mean time, the miſfortune of being out of favour at court, like other miſfortunes, drew after it a train of more. During the courſe of this paper, in which he had aſſumed the feigned name of *Sir John Edgar*, he was outrageouſly attacked by Mr Dennis, the noted critic, in a very abuſive pamphlet, entitled *The Character and Conduct of Sir John Edgar*. To this inſult our author made a proper reply in the Theatre.

While he was ſtruggling with all his might to ſave himſelf from ruin, he found time to turn his pen againſt the miſchievous South-ſea ſcheme, which had nearly

brought

brought the nation to ruin in 1720; and the next year he was reſtored to his office and authority in the play-houſe in Drury-Lane. Of this it was not long before he made an additional advantage, by bringing his celebrated comedy called the *Conſcious Lovers* upon that ſtage, where it was acted with prodigious ſucceſs; ſo that the receipt there muſt have been very conſiderable, beſides the profits accruing by the ſale of the copy, and a purſe of 500l. given to him by the king, to whom he dedicated it. Yet notwithſtanding theſe ample ſupplies, about the year following, being reduced to the utmoſt extremity, he ſold his ſhare in the play-houſe; and ſoon after commenced a law-ſuit with the managers, which in 1726 was decided againſt him. Having now again, for the laſt time, brought his fortune, by the moſt heedleſs profuſion, into a deſperate condition, he was rendered altogether incapable of retrieving the loſs, by being ſeized with a paralytic diſorder, which greatly impaired his underſtanding. In theſe unhappy circumſtances, he retired to his ſeat at Languanor near Caermarthen in Wales, where he died on the 21ſt of September 1729, and was privately interred, according to his own deſire, in the church of Caermarthen. Among his papers were found the manuſcripts of two plays, one called *The Gentlemen*, founded upon the Eunuch of Terence, and the other intitled *The School of Action*, both nearly finiſhed.

Sir Richard was a man of undiſſembled and extenſive benevolence, a friend to the friendleſs, and, as far as his circumſtances would permit, the father of every orphan. His works are chaſte and manly. He was a ſtranger to the moſt diſtant appearance of envy or malevolence; never jealous of any man's growing reputation; and ſo far from arrogating any praiſe to himſelf from his conjunction with Mr Addiſon, that he was the firſt who deſired him to diſtinguiſh his papers. His great fault was want of economy; and it has been ſaid of him, he was certainly the moſt agreeable and the moſt innocent rake that ever trod the rounds of diſſipation.

STEEPLE, an appendage erected generally on the weſtern end of churches, to hold the bells. Steeples are denominated from their form, either ſpires or towers: the firſt are ſuch as aſcend continually diminiſhing either conically or pyramidally; the latter are mere parallelopipeds, and are covered a-top platform-like.

STEERAGE, on board a ſhip, that part of the ſhip next below the quarter-deck, before the bulk-head of the great cabin, where the ſteerſman ſtands, in moſt ſhips of war. See STEERING.

STEERING, in *Navigation*, the art of directing the ſhip's way by the movements of the helm; or of applying its efforts to regulate her courſe when ſhe advances.

The perfection of ſteering conſiſts in a vigilant attention to the motion of the ſhip's head, ſo as to check every deviation from the line of her courſe in the firſt inſtant of its motion; and in applying as little of the power of the helm as poſſible. By this ſhe will run more uniformly in a ſtraight path, as declining leſs to the right and left; whereas, if a greater effort of the helm is employed, it will produce a greater declination from the courſe, and not only increaſe the difficulty of ſteering, but alſo make a crooked and irregular track through the water. See HELM.—The helmſman ſhould diligently watch the movements of the head by the land, clouds, moon, or ſtars; becauſe, although the courſe is in general regulated by the compaſs, yet the vibrations of the needle are not ſo quickly perceived as the ſallies of the ſhip's head to the right or left, which, if not immediately reſtrained, will acquire additional velocity in every inſtant of their motion, and demand a more powerful impulſe of the helm to reduce them; the application of which will operate to turn her head as far on the contrary ſide of her courſe.—The phraſes uſed in ſteering a ſhip vary according to the relation of the wind to her courſe. Thus, if the wind is fair or large, the phraſes uſed by the pilot or officer who ſuperintends the ſteerage are, *port*, *ſtarboard*, and *ſteady*. The firſt is intended to direct the ſhip's courſe farther to the right; the ſecond is to guide her farther to the left; and the laſt is deſigned to keep her exactly in the line whereon ſhe advances, according to the courſe preſcribed. The exceſs of the firſt and ſecond movements is called *hard-a-port*, and *hard-a-ſtarboard*; the former of which gives her the greateſt poſſible inclination to the right, and the latter an equal tendency to the left.—If, on the contrary, the wind is foul or ſcant, the phraſes are *luff*, *thus*, and *no nearer*; the firſt of which is the order to keep her cloſe to the wind; the ſecond, to retain her in her preſent ſituation; and the third to keep her ſails full.

In a ſhip of war, the exerciſe of ſteering the ſhip is uſually divided amongſt a number of the moſt expert ſailors, who attend the helm in their turns; and are accordingly called *timoneers*, from the French term *timonier*, which ſignifies "helmſman." The ſteerage is conſtantly ſuperintended by the quarter-maſters, who alſo attend the helm by rotation. In merchant ſhips every ſeaman takes his turn in this ſervice, being directed therein by the mate of the watch, or ſome other officer.—As the ſafety of a ſhip, and all contained therein, depends in a great meaſure on the ſteerage or effects of the helm, the apparatus by which it is managed ſhould often be diligently examined by the proper officers. Indeed, a negligence in this important duty appears almoſt unpardonable, when the fatal effects which may reſult from it are duly conſidered.

STEEVENS, GEORGE, the moſt ſucceſsful of all the editors and commentators of Shakeſpeare, was born in the year 1735. We know nothing reſpecting his parents, but they appear to have been in affluent circumſtances. Our author received the rudiments of his education at Kingſton-upon-Thames, and had Gibbon the hiſtorian for a companion at that ſchool. From hence he went to Eton, and in a few years was admitted a fellow commoner of King's college, Cambridge; but no mention is made of his peculiar courſe of ſtudies. It appears, however, that he had little reliſh for the mathematics, which lead at Cambridge to academical honours. On the firſt eſtabliſhment of the Eſſex militia, he accepted of a commiſſion; but he ſpent the concluding years of his life in almoſt total ſecluſion from the world, ſeldom mingling with ſociety, but in the ſhops of bookſellers, in the Shakeſpeare gallery, or in the morning converſations of Sir Joſeph Banks.

Although not an original writer, we cannot in juſtice refuſe him a place among the firſt literary characters of the age, when we conſider the works he illuſtrated, and the learning, ſagacity, taſte, and general knowledge which he brought to the taſk. With a verſatility of talents,

lents, he was eminent both by his pen and his pencil, but his chief excellence lay in his critical knowledge of an author's text; and the beft fpecimen of his great abilities is his edition of Shakefpeare, in which he has left every competitor far behind him. He had ftudied the age of Shakefpeare, and employed his perfevering induftry in becoming acquainted with the writings, manners, and laws of that period, as well as the provincial peculiarities, whether of language or cuftoms, which prevailed in different parts of the kingdom, but more particularly in thofe where Shakefpeare paffed the early years of his life. He was continually increafing this ftore of knowledge, by the acquifition of the obfolete publications of a former age, which he fpared no expence to obtain. His critical fagacity and obfervation were conftantly employed in calling forth the hidden meanings of the dramatic bard, and of courfe enlarging the difplay of his beauties. This advantage is apparent from his laft edition of Shakefpeare, which contains fo large a portion of new, interefting, and accumulated inftruction. In preparing it for the prefs, he gave an inftance of activity and perfeverance without example. To this work he exclufively devoted a period of 18 months, during which he left his houfe every morning at one o'clock, going to his friend Mr Ifaac Read's chambers in Barnard's-inn, without any confideration of the weather or the feafon, and there he found a fheet of the Shakefpeare letter-prefs ready for correction. Thus, while the printers flept the editor was awake, by which means he completed, in lefs than 20 months, his fplendid edition of Shakefpeare in 15 vols. octavo; a labour almoft incredible, and by which the energy and perfevering powers of his mind were fully proved.

He probably refted fatisfied with being a commentator from the particular habits of his life, and his devotion to the name of Shakefpeare. But at the fame time he was a claffical fcholar of the firft order, and well acquainted with the belles lettres of Europe. He ftudied ancient and modern hiftory; and particularly that of his own country. His genius was ftrong and original; his wit abundant; his imagination of every colour; and his fentiments enlivened with the moft brilliant expreffions. His eloquence was logical and animated; his defcriptions were fo true to nature, his figures fo curioufly felected, and fo happily grouped, that he might be regarded as a fpeaking Hogarth. He fcattered his wit and his humour too freely around him, and they were not loft for want of gathering.

Mr Steevens had a very handfome fortune, which he managed with difcretion. His generofity was equal to his fortune; and though not profufe of his money to fturdy beggars, few perfons diftributed with more liberality to truly deferving objects. He poffeffed all the graces of outward accomplifhment, at a period when civility and politenefs were characteriftics of a gentleman.

He bequeathed his valuable Shakefpeare, illuftrated with about 1500 prints, to Lord Spencer; his Hogarth perfect, with the exception of one or two pieces, to Mr Windham; and his corrected copy of Shakefpeare, with 200 guineas, to his friend Mr Read. He died in the month of January 1800, about 65 years of age.

STEGANOGRAPHY, the art of fecret writing, or of writing in ciphers, known only to the perfons correfponding. See CIPHER.

STELLARIA, a genus of plants belonging to the clafs decandria, and in the natural fyftem arranged under the 22d order, *Caryophylleæ*. See BOTANY *Index*.

STELLATE, in *Botany*, a term applied to leaves which grow not lefs than fix at a joint, and are arranged like the rays of a ftar.

STELLERA, GERMAN GROUNDSEL, a genus of plants belonging to the clafs octandria; and in the natural fyftem arranged under the 31ft order, *Vepreculæ*. See BOTANY *Index*.

STELLIONATE, in the civil law, a kind of crime committed by a fraudulent bargain, where one of the parties fells a thing for what it is not; as if I fell an eftate for my own which belongs to another, or convey a thing as free and clear which is already engaged to another, or put off copper for gold, &c.

STEM, in *Botany*, that part of a plant arifing out of the root, and which fuftains the leaves, flowers, fruits, &c. By wafhing and rubbing the ftems of trees, their annual increafe is promoted; for the method of doing which, fee the article TREE.

STEM of a Ship, a circular piece of timber into which the two fides of a fhip are united at the fore-end: the lower end of it is fcarfed to the keel, and the bowfprit refts upon its upper end. The ftem is formed of one or two pieces, according to the fize of the veffel; and as it terminates the fhip forward, the ends of the wales and planks of the fides and bottom are let into a groove or channel, in the midft of its furface, from the top to the bottom; which operation is called *rabiting*. The outfide of the ftem is ufually marked with a fcale, or divifion of feet, according to its perpendicular height from the keel. The intention of this is to afcertain the draught of water at the forepart, when the fhip is in preparation for a fea-voyage, &c. The ftem at its lower end is of equal breadth and thicknefs with the keel, but it grows proportionally broader and thicker towards its upper extremity. See *SHIP-Building*.

STEMMATA, in the hiftory of infects, are three fmooth hemifpheric dots, placed generally on the top of the head, as in moft of the hymenoptera and other claffes. The name was firft introduced by Linnæus.

STEMODIA, a genus of plants belonging to the clafs didynamia; and in the natural fyftem ranging under the 40th order, *Perfonatæ*. See BOTANY *Index*.

STEMPHYLA, a word ufed by the ancients to exprefs the hufks of grapes, or the remains of the preffings of wine. The fame word is alfo ufed by fome to exprefs the remaining mafs of the olives, after the oil is preffed out.

STEMPHYLITES, a name given by the ancients to a fort of wine preffed hard from the hufks.

STEMPLES, in mining, crofs bars of wood in the fhafts which are funk to mines.

In many places the way is to fink a perpendicular hole, or fhaft, the fides of which are ftrengthened from top to bottom with wood-work, to prevent the earth from falling in; the tranfverfe pieces of wood are called *ftemples*, and by means of thefe the miners in fome places defcend, without ufing any rope.

STEMSON, in a fhip, an arching piece of timber fixed within the apron, to reinforce the fcarf thereof, in the fame manner as the apron fupports the fcarf of the ftern. In large fhips it is ufually formed of two pieces.

STENOGRAPHY (A).

CHAP. I.

THE art of ſtenography, or ſhort writing, was known and practiſed by moſt of the ancient civilized nations. The Egyptians, who were diſtinguiſhed for learning at an early period, at firſt expreſſed their words by a delineation of figures called *hieroglyphics*. A more conciſe mode of writing ſeems to have been afterwards introduced, in which only a part of the ſymbol or picture was drawn. This anſwered the purpoſe of ſhort-hand in ſome degree. After them the Hebrews, the Greeks, and the Romans *, adopted different methods of abbreviating their words and ſentences, ſuited to their reſpective languages. The initials, the finals, or radicals, often ſerved for whole words; and various combinations of theſe ſometimes formed a ſentence. Arbitrary marks were likewiſe employed to determine the meaning, and to aſſiſt legibility; and it ſeems probable that every writer, and every author of antiquity, had ſome peculiar method of abbreviation, calculated to facilitate the expreſſion of his own ſentiments, and intelligible only to himſelf.

* Vide *Buxtorf*, *Diog. Laertius*, *Plutarch*, &c.

It is alſo probable, that ſome might by theſe means take down the heads of a diſcourſe or oration; but few, very few, it is preſumed, could have followed a ſpeaker through all the meanders of rhetoric, and noted with preciſion every ſyllable, as it dropt from his mouth, in a manner legible even to themſelves.

To arrive at ſuch conſummate perfection in the art was reſerved for more modern times, and is ſtill an acquiſition by no means general.

In every language of Europe, till about the cloſe of the 16th century, the Roman plan of abbreviating (viz. ſubſtituting the initials or radicals, with the help of arbitraries, for words) appears to have been employed. Till then no regular alphabet had been invented expreſsly for ſtenography, when an Engliſh gentleman of the name of *Willis* invented and publiſhed one (B). His plan was ſoon altered and improved, or at leaſt pretended to be ſo. One alteration ſucceeded another; and at intervals, for a ſeries of years paſt, ſome men of ingenuity and application have compoſed and publiſhed ſyſtems of ſtenography, and doubtleſs have themſelves reaped all the advantages that attend it. But among the various methods that have been propoſed, and the different plans that have been adopted by individuals, none has yet appeared fortunate enough to gain general approbation; or proved ſufficiently ſimple, clear, and conciſe, to be univerſally ſtudied and practiſed.

Some ſyſtems are replete with unmeaning ſymbols, perplexing arbitraries, and ill-judged contractions; which render them ſo difficult to be attained by a common capacity, or ordinary application, that it is not to be wondered at if they have ſunk into neglect, and are now no longer known (C). Other ſyſtems, by being too prolix, by containing a multiplicity of characters, and thoſe characters not ſimple or eaſily remembered, become ineffectual to the purpoſe of expedition, and are only ſuperior in obſcurity to a common hand. Some, again, not only reject all arbitraries and contractions, but even prepoſitions and terminations; which laſt, if not too laviſhly employed and badly deviſed, highly contribute to promote both expedition and legibility; and though they reduce their characters to fewer than can poſſibly expreſs the various modifications of ſound, yet they make nearly one half of them complex. In the diſpoſition of the vowels, there is the greateſt perplexity in moſt ſyſtems. A dot is ſometimes ſubſtituted for all the vowels indiſcriminately, and the judgement is left to determine which letter out of ſix any dot is intended to expreſs; or a minute ſpace is allotted them; ſo that unleſs they be arranged with mathematical preciſion they cannot be diſtinguiſhed from one another; but ſuch a minute attention is inconſiſtent with the nature of ſhort-hand, which ſhould teach us to write down in a ſhort time, as well as in ſmall bounds, what we wiſh to preſerve of what we hear. Nor is the plan of lifting the pen and putting the next conſonant in the vowel's place, in the middle of words, leſs liable to objections; or that of repreſenting all the vowels by diſtinct characters, being obviouſly ill calculated for facility and diſpatch,

(A) The value of ſtenography is not unknown to the learned; and the care and ſucceſs with which it has been lately cultivated in theſe kingdoms will, in all probability, ſoon render it an object of general attention. No one, however, appears to us to have ſimplified and improved the art ſo much as Dr Mavor, author of *Univerſal Stenography*, who has liberally permitted us to preſent our readers with a complete view of his ſcheme. To thoſe who wiſh to become proficients in SHORT-WRITING, we earneſtly recommend his entire publication (printed for Cadell and Davis, Strand, London), which in many ſchools of the firſt reputation now forms a deſerved claſs-book.

(B) Mr Locke ſays, a regular method of ſhort-writing ſeems to be known and practiſed only in Britain. This is not now the caſe; and indeed there is no reaſon to doubt whether characters may not be invented to expreſs the various ſounds, or letters, employed in any language, either ancient or modern.

(C) A liſt of writers on ſtenography. Mr Addy, Alridge, Angell, Annet, Blandemore, Bloſſet, Botley, Bridges, Byrom, Coles, Croſs, Dix, Everardt, Ewen, Facey, Farthing, Gibbs, Græme, Gurney, Heath, Holdſworth, Hopkins, Jeake, Labourer, Lane, Lyle, Macauley, Maſon, Mavor, Metcalfe, Nicholas, Palmer, Rich, Ridpath, Shelton, Steele, Tanner, Taylor, Thickneſſe, Tiffen, Webſter, Weſton, Williamſon, Willis, B. D. and Willis, &c.

diſpatch, and conſequently inadmiſſible into any uſeful ſyſtem.

It is to be confeſſed, that the perſon who firſt propoſed the omiſſion of vowels in the middle of words (D), which it is obvious are not wanted, and invented letters, which could be connected as in a running hand without lifting the pen in the middle of the word, made a real improvement on the works of his predeceſſors. But, in fine, moſt ſyſtems, either in their plan or execution, labour under ſome capital defect, attended with circumſtances highly diſcouraging to the learner, and which in a great meaſure defeat the end of their invention, by being too complicated to be learned with eaſe and remembered with accuracy, or to be practiſed with the expedition which is requiſite; and ſo difficult to be deciphered, that a man can ſcarcely read what he has juſt written.

To obviate theſe defects; to provide againſt prolixity and conciſeneſs, which might occaſion obſcurity; to exhibit a ſyſtem founded on the ſimpleſt principles, which might be eaſily learned and read, and yet be capable of the utmoſt expedition—were the motives that gave riſe to the preſent attempt.

This method will be found different from any yet publiſhed, and ſuperior to all in the diſpoſition of the vowels and the facility of arranging them; the confuſion in placing which ſeems to detract from the merit of the beſt performances on the ſubject; and it may be affirmed, without oſtentation, that characters ſimpler in their form, and more perfect in their union, have not been applied to the art of ſtenography.

As well as it could be determined, the ſimpleſt characters are appropriated to the letters moſt uſually employed: indeed, as far as poſſible, thoſe which are complex have been rejected; but as it was an object always kept in view that the writing ſhould be on a line, a few are admitted into the alphabet for that reaſon.

The characters for the double and triple conſonants are the eaſieſt that could be invented, conſiſtent with perſpicuity (E); for care has been taken to provide againſt all obſcurity which might ariſe by adopting letters too ſimilar in their formation; and with reſpect to the prepoſitions and terminations, thoſe which occur moſt frequently are expreſſed by the ſimpleſt characters, which will be found perfectly eaſy in their application.

The arbitraries are few in number (F), and the arbitrary abbreviations, as they are entirely from the letters of the alphabet, and choſen from ſome thouſands of words in common uſe, will well repay the learner for an hour's trouble in committing them to memory.

The laſt chapter lays down a ſcheme of abbreviation, compriſed in a few rules, perfectly eaſy to be underſtood and practiſed by proficients in this art, which we hope will anſwer the expectation of the author, and will be found free from the perplexity complained of in many ſyſtems where abbreviation is admitted. The principal rules are new, are ſo eaſy, ſo extenſive in their uſe, and ſo conſiſtent with expedition and legibility, if applied with judgement, that they alone might ſuffice. The learner is however adviſed by no means to adopt any of them, till experience has convinced him that they may be uſed without error or injury to legibility. All abbreviating rules are ſuited to thoſe only who have made ſome progreſs in the ſtenographic art; for although they certainly promote expedition in a wonderful manner, and afford the greateſt eaſe to a proficient, yet a learner, as expedition is not his firſt, though his ultimate view, ſhould admit of nothing that in the leaſt renders the reading difficult.

CHAP. II.

THE Engliſh alphabet conſiſts of twenty-ſix letters; ſix of which are vowels, *a*, *e*, *i*, *o*, *u*, and *y*; and the other twenty conſonants, *b*, *c*, *d*, *f*, *g*, *h*, *k*, *l*, *m*, *n*, *p*, *q*, *r*, *s*, *t*, *v*, *x*, and *z*. 1 The general principles of ſtenography.

This alphabet, as is obſerved by the beſt grammarians that have written on the language, is both defective and redundant in expreſſing the various modifications of ſound *.

* *Lowth's Gram. Prieſtley's Gram. Sheridan's Lectures on Elocution.*

Cuſtom or prejudice has aſſigned ſome letters a place, when others would with much more propriety expreſs the ſame ſound: and to this may be added, that ſeveral letters, ſometimes in one word, ſeem to be admitted for no other reaſon than to perplex a young beginner or a foreigner, as an obſtruction to true pronunciation, and to add to the apparent length of the word, when they are entirely quieſcent and uſeleſs. That this is the genius of the orthography of our language muſt be perceived by the moſt ſuperficial obſerver; but no modern tongue is abſolutely free from the ſame exceptions. In particular, the French has a great number of dormant letters, which, it is obvious, render the pronunciation more difficult and perplexing to learners (G).

But as it is neither our buſineſs nor our intention to propoſe a mode of ſpelling different from that in common uſe, when applied to printing or long-hand writing (ſince ſeveral innovators in orthography have fallen into contempt, and their plans have been only preſerved as beacons to warn others of the folly of endeavouring to ſubvert eſtabliſhed principles †); we ſhall only obſerve, that in ſtenography, where the moſt expeditious and conciſe

† *Preface to Johnſon's Dictionary.*

(D) Mr Byrom rejected vowels entirely in the middle of words, as others before him had only done partially. Without critically examining the executive part of his performance, which is very defective, it muſt be owned, that it is above the reach of human ingenuity to exceed his general plan; which for ever muſt be the baſis of every future rational ſyſtem.

(E) Thoſe for *th* and *ch* may be either made upright or ſloping to the right.

(F) Theſe are not by any means preſcribed; they may be employed or not according to the fancy of the learner.

(G) The Latin and Greek claim a juſt ſuperiority over every modern tongue in this reſpect. In them no confuſion or doubt can ariſe from the manner of ſpelling; and the reader can ſcarcely be wrong (unleſs in quantity) in ſounding all the letters he ſees.

conciſe method is the beſt, if conſiſtent with perſpicuity, the following ſimple rules are ſtudiouſly to be regarded and practiſed.

2 Rules for the conſonants.

RULE I. All quieſcent conſonants in words are to be dropped; and the orthography to be directed only by the pronunciation: which being known to all, will render this art attainable by thoſe who cannot ſpell with preciſion in long hand.

RULE II. When the abſence of conſonants, not entirely dormant, can be eaſily known, they may often be omitted without the leaſt obſcurity.

RULE III. Two or ſometimes more conſonants may, to promote greater expedition, be exchanged for a ſingle one of nearly ſimilar ſound; and no ambiguity as to the meaning enſue (H).

RULE IV. When two conſonants of the ſame kind or ſame ſound come together, without any vowel between them, only one is to be expreſſed; but if a vowel or vowels intervene, both are to be written: only obſerve, if they are perpendicular, horizontal, or oblique lines, they muſt only be drawn a ſize longer than uſual; and characters with loops muſt have the ſize of their heads doubled *.

* See Plate DVII.

3 Firſt rule exemplified.

Might is to be written *mit*, fight *fit*, machine *maſhin*, enough *enuf*, laugh *laf*, prophet *profet*, phyſics *fiſiks*, through *thro'*, foreign *foren*, ſovereign *ſoveren*, pſalm *ſam*, receipt *reſet*, write *rite*, wright *rit*, iſland *iland*, knavery *navery*, temptation *temtation*, knife *nife*, ſtick *ſtik*, thigh *thi*, honour *onour*, indictment *inditement*, acquaint *aquaint*, chaos *kaos*, &c.

4 Second rule exemplified.

Strength *ſtrenth*, length *lenth*, friendſhip *frenſhip*, connect *conek*, commandment *comanment*, conjunct *conjunt*, humble *humle*, lumber *lumer*, ſlumber *ſlumer*, number *numer*, exemplary *exemlary*, &c.

5 Third rule exemplified.

Rocks *rox*, acts *aks* or *ax*, facts *faks* or *fax*, diſtricts *diſtriks*, or *diſtrix*, affects *afeks* or *afex*, afflicts *afliks* or *aflix*, conquer *konkr*, &c.

6 Fourth rule exemplified.

Letter *leter*, little *litle*, command *comand*, error *eror*, terror *teror*, &c. But in *remember*, *moment*, *ſiſter*, and ſuch like words, where two conſonants of the ſame name have an intervening vowel, both of them muſt be written.

Theſe four rules, with their examples, being carefully conſidered by the learner, will leave him in no doubt concerning the diſpoſition and management of the conſonants in this ſcheme of ſhort-writing; we ſhall therefore proceed to lay down rules for the application of the vowels with eaſe and expedition.

7 Rules for the vowels.

RULE I. Vowels, being only ſimple articulate ſounds, though they are the connectives of conſonants, and employed in every word and every ſyllable, are not neceſſary to be inſerted in the middle of words; becauſe the conſonants, if fully pronounced, with the aſſiſtance of connection, will always diſcover the meaning of a word, and make the writing perfectly legible.

RULE II. If a vowel is not ſtrongly accented in the incipient ſyllable of a word, or if it is mute in the final, it is likewiſe to be omitted; becauſe the ſound of the incipient vowel is often implied in that of the firſt conſonant, which will conſequently ſupply its place.

RULE III. But if the vowel conſtitutes the firſt or laſt ſyllable of a word, or is ſtrongly accented at its beginning or end, that vowel is continually to be written.

RULE IV. If a word begins or ends with two or more vowels though ſeparated, or when there is a coalition of vowels, as in diphthongs and triphthongs; only one of them is to be expreſſed, which muſt be that which agrees beſt with the pronunciation.

RULE V. In monoſyllables, if they begin or end with a vowel, it is always to be inſerted, unleſs the vowel be *e* mute at the end of a word.

Such are the general principles of this art; in vindication and ſupport of which it will be needleſs to offer any arguments, when it is conſidered that brevity and expedition are the chief objects, if conſiſtent with legibility; and the ſubſequent ſpecimens in the orthography recommended will, we hope, be ſufficient to ſhow that there is no real deficiency in the laſt-mentioned particular.

8 Specimen of the mode of ſpelling in ſtenography.

He who md us mſt be etrnl, grt, nd mnptnt. It is or dty, as rſnl bngs, to ſrv, lv, nd oby hm.—A mn tht wd avd blm, ſhd be ſrkmſpk in al hs axns, nd ndvr wth al hs mt to pls evry bdy.—I wd nt frm any knxns wth a mn who hd no rgrd fr hmslf; nthr wd I blv a mn who hd ons tld me a li.—Onr is of al thngs the mſt dfklt to prſrv ntrnſhd; nd whn ons mpchd, lk the chſty of a wmn, nvr ſhns wth its wntd lſtr.—Wth gd mnrs, kmplſms nd an eſy plt adrs, mny mk a fgr in the wrl, whs mnl ablts wd ſkrſly hv rsd thm aby the rnk of a ſtmn.—Idlns is the prnt of a thſnd msfrtns, wch ar nvr flt by the ndſtrs: it is a pn nd a pnſhmnt of itslf, nd brngs wnt nd bgry in its trn.—Vrtu is the frſt thng tht ſhd be rgrdd; it is a rwrd of itslf; mks a mn rſpktbl hr, nd wl mk hm etrnly hpy hrftr.—Prd is a mſt prnſs psn, wch yt ws plntd by hvn in ur ntr, to rs ur emlsn to imtt grt nd wrthy krktrs or axns, to xt in us a sl fr wht is rt nd gſt, nd a ldbl ndgnſn gnſt oprſrs nd wrks of any knd of nkyty; in ſhrt, to mk us st a prpr vlu upn urvſls, nd dſps a wrthls flo, hu evr xltd. Ths fr prd is a vrtu, nd my gſtly be kld a grtns of ſl. Bt prd, lk othr pſns, gnrly fxs upon rng obgks, or is apld in rng prprſns. Hu kmn is it to ſe a rtch whm evry vs hs rndrd mſrbl, nd evry fly kntmtbl, vlng hmſlf on hs hi brth, nd bſtng ths ilſtrs nſttrs, of whm he nhrts nthng bt the nm or ttl! nſtrs who if thy nu hm, wd dſn thr dſndnt wth kntmt. But al prd of ths ſrt is fly, nd evr to be avdd.

CHAP. III.

As the whole of this art depends upon a regular method and a ſimple alphabet, we have not only endeavoured to eſtabliſh the former on ſatisfactory principles, but have been careful to appropriate, according to the comparative frequency of their occurrence, ſuch characters

(H) By this rule likewiſe *q* and *v* in the middle of words, but never in the beginning, may be exchanged for *k* and *f*, when they admit of an eaſier connecting with the following character, or will make the writing appear neater.

ters for the letters as, after repeated trials and alterations, were conceived to be the beſt adapted for diſpatch.

9 Stenographic alphabet. Plate DVII.

The ſtenographic alphabet conſiſts of 18 diſtinct characters (viz. two for the vowels and the reſt for the conſonants), taken from lines and ſemicircular curves; the formation and application of which we ſhall now explain, beginning with the vowels.

For the three firſt vowels, *a*, *e*, and *i*, a comma is appropriated in different poſitions; and for the other three, *o*, *u*, and *y*, a point. The comma and point, when applied to *a*, and *o*, is to be placed, as in the Plate DVII. at the top of the next character; when for *e* and *u*, oppoſite to the middle; and when for *i* and *y*, at the bottom.

This arrangement of the vowels is the moſt ſimple and diſtinct that can eaſily be imagined. Places at the top, the middle, and the bottom of characters, which make three different poſitions, are as eaſily diſtinguiſhed from one another as any three ſeparate characters could be; and a comma is made with the ſame facility as a point.

10 Lines.

Simple lines may be drawn four different ways; perpendicular, horizontal, and with an angle of about 45 degrees to the right and left. An aſcending oblique line to the right, which will be perfectly diſtinct from the reſt when joined to any other character, may likewiſe be admitted. Theſe characters being the ſimpleſt in nature, are aſſigned to thoſe five conſonants which moſt frequently occur, viz. *l*, *r*, *t*, *c* hard or *k*, and *c* ſoft or *s*.

11 Circles.

Every circle may be divided with a perpendicular and horizontal line, ſo as to form likewiſe four diſtinct characters. Theſe being the next to lines in the ſimplicity of their formation, we have appropriated them for *b*, *d*, *n*, and *m*.

12 Curves and lines.

The characters expreſſing nine of the conſonants are all perfectly diſtinct from one another; eight only remain which are needful, viz. *f*, *g* or *j*, *h*, *p*, *q*, *v*, *w*, and *x*; to find characters for which we muſt have recourſe to mixed curves and lines. The characters which we have adopted are the ſimpleſt in nature after thoſe already applied, admit of the eaſieſt joining, and tend to preſerve lineality and beauty in the writing.

It muſt be obſerved that we have no character for *c* when it has a hard ſound, as in *caſtle*; or ſoft, as in *city*; for it naturally takes the ſound of *k* or *s*, which in all caſes will be ſufficient to ſupply its place.

R likewiſe is repreſented by the ſame character as *l*; only with this difference, *r* is written with an aſcending ſtroke (I), and *l* with a deſcending; which is always to be known from the manner of its union with the following character; but in a few monoſyllables where *r* is the only conſonant in the word, and conſequently ſtands alone, it is to be made as is ſhown in the alphabet for diſtinction's ſake.

Z, as it is a letter ſeldom employed in the Engliſh language, and only a coarſer and harder expreſſion of *s*, muſt be ſupplied by *s* whenever it occurs; as for *Zedekiah* write *Sedekiah*, &c.

CHAP. IV.

13 Rules for prepoſitions and terminations.

The prepoſitions and terminations in this ſcheme are ſo ſimple, that the greateſt benefit may be reaped from them, and very little trouble required to attain them; as the incipient letter or the incipient conſonant of all the prepoſitions and of ſeveral of the terminations is uſed to expreſs the whole. But although in Plate DVII. ſufficient ſpecimens are given of the manner of their application, that the learner of leſs ingenuity or more ſlow perception may have every aſſiſtance, we have ſubjoined the following directions.

Rule I. The prepoſition is always to be written without joining, yet ſo near as plainly to ſhow what word it belongs to; and the beſt way is to obſerve the ſame order as if the whole was to be connected.

Rule II. A prepoſition, though the ſame letters that conſtitute it may be met with in the middle or end of a word, is never to be uſed, becauſe it would expoſe to obſcurity.

Rule III. Obſerve that the prepoſition *omni* is expreſſed by the vowel *o* in its proper poſition; and for *anti*, *anta*, *ante*, by the vowel *a*, which the radical part of the word will eaſily diſtinguiſh from being only ſimple vowels.

The firſt rule for the prepoſitions is (allowing ſuch exceptions as may be ſeen in the Plate) to be obſerved for the terminations; and alſo the ſecond, *mutatis mutandis*; except that whenever *ſis*, *ſus*, *ſys*, *cious*, *tious*, and *ces* occur, they are to be expreſſed as directed in the fourth rule for the conſonants, whether in the beginning, middle, or end of words (K).

Rule IV. The terminative character for *tion*, *ſion*, *cion*, *cian*, *tian*, is to be expreſſed by a ſmall circle joined to the neareſt letter, and turned to the right; and the plurals *tions*, *ſions*, *cions*, *cians*, *tians*, *tience*, by a dot on the ſame ſide.

Rule V. The terminative character for *ing*, is to be expreſſed likewiſe by a ſmall circle, but drawn to the left hand; and its plural *ings* by a dot (L).

Rule VI. The plural ſign *s* is to be added to the terminative characters when neceſſary.

Rule VII. The ſeparated terminations are never to be uſed but in polyſyllables or words of more ſyllables than one.

Theſe rules duly obſerved will point out a method as conciſe and elegant as can be deſired, for expreſſing the moſt

(I) The character for *h*, when lineality requires it, may be made from the bottom and inverted (ſee Plate DVII.) And often *h* may be omitted entirely, or a vowel may be ſubſtituted in its ſtead, without any injury to legibility, it being rather a breathing than letter.

(K) But in a few words where three horizontal characters meet, it will be better to expreſs the *ſis*, &c. by the ſemielliptical character in Plate DVII. oppoſite *tious*.

(L) In horizontal characters, by the left hand is meant the top, and by the right the ſpace below the letter (ſee *ing* joined, Plate DVII.). In all other characters the right and left poſitions will naturally be known.

moſt frequent and longeſt prepoſitions and terminations in the Engliſh language. If it ſhould be thought neceſſary to increaſe their number by the addition of others, it will be an eaſy matter for any one of the leaſt diſcernment to do ſo, by proceeding on the principles before laid down.

CHAP. V.

14 Rules for abbreviation. THOUGH a more conciſe method of writing, or more numerous abbreviations, may not be indiſpenſably neceſſary, if the foregoing directions be practiſed for a conſiderable time, yet contractions will be found extremely uſeful and convenient to thoſe who have attained a proper knowledge of the ſubject, and lead to a greater degree of expedition, at the ſame time that they diminiſh the labour of writing. It has been obſerved in the introduction, that abbreviations are only to be employed by proficients in this art; becauſe expedition is not the firſt, though the ultimate, object in view; and that an eaſy legibility is of the utmoſt conſequence to the learner; which, however, cannot be preſerved, if he adopts too ſoon thoſe very rules which in time will afford him the greateſt eaſe when applied with judgement.

The following ſhort and practical rules will be found, we hope, fully adequate to every purpoſe for which they were intended, and are far ſuperior in the facility of their application to any which we have ſeen.

RULE I. The uſual abbreviations in long hand are always to be followed; as Mr for Maſter, M. D. for Doctor of Phyſic, and Abp. for Archbiſhop, &c.

RULE II. Subſtantives, adjectives, verbs, and participles, when the ſenſe will direct to the meaning, are to be expreſſed by their initial conſonant with the diſtinguiſhing marks exhibited in Plate DVII. viz. a ſubſtantive muſt have the dot exactly over its initial conſonant; an adjective muſt have a dot under it; a verb is to be expreſſed by a comma over its initial conſonant; and a participle by a comma under (M). Theſe being the four principal parts of ſpeech will be ſufficient; and an adept will never be at a loſs to know when he can with ſafety apply this rule to them.

RULE III. To render the writing more legible, the laſt letter of the word may be joined to the firſt, and the proper mark applied.

RULE IV. The conſtituent or radical part of words, eſpecially if they are long, will often ſerve for the whole, or ſometimes the firſt ſyllable: as, we ought to moderate our *ex.* by our *circum.*; a man's *man.* commonly ſhape his *for.*

RULE V. All long words without exception may have their prepoſitions or terminations expreſſed by the incipient conſonant of ſuch prepoſition or termination.

RULE VI. When there is a great dependence between the parts of a ſentence, the initial letter will often ſuffice; as *L.* is the capital of Great *B.*; the eldeſt *S.* of the king of Great *B.* is ſtyled prince of *W.* Every one, it is preſumed, will allow this to be perfectly legible in long-hand, then why may it not in ſtenography?

RULE VII. The terminations *neſs* and *leſs* may be omitted; as *faithfulneſs* is only to be written *faithful*; *forwardneſs*, *forward*; *heedleſs*, *heed*; *ſtubbornneſs*, *ſtubborn*, &c.

RULE VIII. The ſecond and third perſons of verbs, ending in *eth* and *eſt*, may be expreſſed by *s*; as, he *loves*, thou *teaches*; inſtead of he *loveth*, thou *teacheſt*: or even without *s*; as, he *love*, &c.

RULE IX. Words may often be entirely omitted, and yet no ambiguity enſue; as, *In beginning God created heaven and earth*, for In *the* beginning God created *the* heaven and *the* earth.

RULE X. When there is an immediate repetition of a ſentence or word, a line is to be drawn under the ſentence or word to be repeated; as, Amen, Amen, is to be written *Amen*; but if any words intervene before a word or ſentence is to be repeated, the line muſt be drawn as before, and a ʌ or mark of omiſſion placed where the repetition ſhould begin; as, *Is it juſt the innocents ſhould be* condemned ʌ reviled?

The CONTENTS of the STENOGRAPHIC PLATES.

Fabricius's Reply to Pyrrhus.

As to my poverty, you have indeed, Sir, been rightly informed. My whole eſtate conſiſts in a houſe of but mean appearance, and a little ſpot of ground, from which by my own labour I draw my ſupport. But if by any means you have been perſuaded to think, that this poverty makes me leſs conſidered in my country, or in any degree unhappy, you are extremely deceived. I have no reaſon to complain of fortune, ſhe ſupplies me with all that nature requires; and if I am without ſuperfluities, I am alſo free from the deſire of them. With theſe I confeſs I ſhould be more able to ſuccour the neceſſitous, the only advantage for which the wealthy are to be envied; but as ſmall as my poſſeſſions are, I can ſtill contribute ſomething to the ſupport of the ſtate and the aſſiſtance of my friends. With regard to honours, my country places me, poor as I am, upon a level with the richeſt: for Rome knows no qualifications for great employments but virtue and ability. She appoints me to officiate in the moſt auguſt ceremonies of religion; ſhe entruſts me with the command of her armies; ſhe confides to my care the moſt important negotiations. My poverty does not leſſen the weight and influence of my counſels in the ſenate; the Roman people honour me for that very poverty which you conſider as a diſgrace; they know the many opportunities I have had in war to enrich myſelf without incurring cenſure; they are convinced of my diſintereſted zeal for their proſperity; and if I have any thing to complain of in the return they make, it is only the exceſs of their applauſe. What value then can I ſet upon your gold and ſilver! What king can add any thing to my fortune! Always attentive to diſcharge the duties incumbent

Plate DVIII.

(M) The dot or comma being placed thus will never occaſion them to be miſtaken for vowels, becauſe they ſhould always be on one ſide or other; whereas the mark for parts of ſpeech may conſtantly be placed exactly over or under.

incumbent on me, I have a mind free from ſelf-reproach, and I have an honeſt fame. *Dodſley's Preceptor.*

Letter to a Friend againſt waſte of Time.

Converſe often with yourſelf, and neither laviſh your time, nor ſuffer others to rob you of it. Many of our hours are ſtolen from us, and others paſs inſenſibly away; but of both theſe loſſes the moſt ſhameful is that which happens through our own neglect. If we take the trouble to obſerve, we ſhall find that one conſiderable part of our life is ſpent in doing evil, and the other in doing nothing, or in doing what we ſhould not do. We don't ſeem to know the value of time, nor how precious a day is; nor do we conſider that every moment brings us nearer our end. Reflect upon this, I entreat you, and keep a ſtrict account of time. Procraſtination is the moſt dangerous thing in life. Nothing is properly ours but the inſtant we breathe in, and all the reſt is nothing; it is the only good we poſſeſs; but then it is fleeting, and the firſt comer robs us of it. Men are ſo weak, that they think they oblige by giving of trifles, and yet reckon that time as nothing for which the moſt grateful perſon in the world can never make amends. Let us therefore conſider time as the moſt valuable of all things; and every moment ſpent, without ſome improvement in virtue or ſome advancement in goodneſs, as the greateſt ſublunary loſs.

St Paul's Speech before Agrippa and Feſtus.

I think myſelf happy, King Agrippa, that I ſhall anſwer for myſelf this day before thee, touching all things whereof I am accuſed of the Jews: eſpecially becauſe I know thee to be expert in all cuſtoms and queſtions which are among the Jews, wherefore I beſeech thee to hear me patiently. My manner of life from my youth, which was at firſt among mine own nation at Jeruſalem, know all the Jews, which knew me from the beginning (if they would teſtify), that, after the ſtraiteſt ſect of our religion I lived a Phariſee. And now I ſtand and am judged for the hope of the promiſe made by God unto our fathers: unto which promiſe our twelve tribes inſtantly ſerving God day and night hope to come; for which hope's ſake, King Agrippa, I am accuſed of the Jews. Why ſhould it be thought a thing incredible with you, that God ſhould raiſe the dead, when God himſelf has given aſſurance of it unto all men, in that he hath raiſed Chriſt from the dead? As for my own part, moſt noble Feſtus, I own I once verily thought that even I myſelf ought to do many things contrary to the name of Jeſus of Nazareth. Which thing I alſo did in Jeruſalem. I puniſhed the ſaints oft in every ſynagogue, and compelled them to blaſpheme; and being exceedingly mad againſt them, I perſecuted them even unto ſtrange cities. In purſuit of which, as I went to Damaſcus, with authority and commiſſion from the chief prieſts: At mid-day, O king, I ſaw in the way a light from heaven, above the brightneſs of the ſun, ſhining about me, and them which journeyed with me. And when we were all fallen to the earth, I heard a voice ſpeaking unto me, and ſaying in the Hebrew tongue, Saul, Saul, why perſecuteſt thou me? It is hard for thee to kick againſt the pricks. And I ſaid, Who art thou, Lord? And he ſaid, I am Jeſus whom thou perſecuteſt. But riſe, and ſtand upon thy feet: for I have appeared unto thee for this purpoſe, to make thee a miniſter and a witneſs both of theſe things which thou haſt ſeen, and of thoſe things in which I will appear unto thee. Whereupon, O king Agrippa, I was not diſobedient to the heavenly viſion: but ſhewed firſt unto them of Damaſcus, and at Jeruſalem, and throughout all the coaſts of Judea, and then to the Gentiles, that they ſhould repent and turn to God. For theſe cauſes the Jews caught me in the temple, and went about to kill me. Having therefore obtained help of God, I continue unto this day, witneſſing both to ſmall and great, ſaying none other things than thoſe which the prophets and Moſes did ſay ſhould come: That Chriſt ſhould ſuffer, and that he ſhould be the firſt that ſhould riſe from the dead, and ſhould ſhow light unto the people, and to the Gentiles. This is the real truth: Believe me, I am no peſtilent fellow, nor mover of ſedition; but always endeavour all that lies in me to preſerve a conſcience void of offence towards God and towards man: nor can the Jews prove the things whereof they now accuſe me. Neither am I, Feſtus, beſides myſelf; but ſpeak thus freely before the king, becauſe he knows theſe things to be fact; yea, I am fully perſuaded the king knows them all to be fact; for they were not done in a corner. King Agrippa, believeſt thou the prophets? I know that thou believeſt. And would to God that not only thou, but alſo all that hear me this day, were altogether ſuch as I am except theſe bonds. *Holmes's Rhetoric.*

Pope to Atterbury.

Once more I write to you as I promiſed, and this once I fear will be the laſt; the curtain will ſoon be drawn between my friend and me, and nothing left but to wiſh you a long good night; may you enjoy a ſtate of repoſe in this life not unlike that ſleep of the ſoul which ſome have believed is to ſucceed it, where we lie utterly forgetful of that world from which we are gone, and ripening for that to which we are to go. If you retain any memory of the paſt, let it only image to you what has pleaſed you beſt; ſometimes preſent a dream of an abſent friend, or bring you back an agreeable converſation. But, upon the whole, I hope you will think leſs of the time paſt than the future; as the former has been leſs kind to you than the latter infallibly will be. Do not envy the world your ſtudies: They will tend to the benefit of men, againſt whom you can have no complaint; I mean, of all poſterity: and, perhaps, at your time of life, nothing elſe is worth your care. What is every year of a wiſe man's life but a cenſure or critic on the paſt? Thoſe whoſe date is the ſhorteſt, live long enough to laugh at one half of it: The boy deſpiſes the infant, the man the boy, the philoſopher both, and the Chriſtian all. You may now begin to think your manhood was too much a puerility; and you will never ſuffer your age to be but a ſecond infancy. The toys and baubles of your childhood are hardly now more below you than thoſe toys of our riper and our declining years; the drums and rattles of ambition, and the dirt and bubbles of avarice. At this time, when you are cut off from a little ſociety, and made a citizen of the world at large, you ſhould bend your talents not to ſerve a party, or a few, but all mankind. Your genius ſhould mount above that miſt, in which its participation and neighbourhood with earth hath long involved it: To ſhine abroad, and to heaven, ought

ought to be the bufinefs and the glory of your prefent fituation. Remember it was at fuch a time that the greateft lights of antiquity dazzled and blazed the moft; in their retreat, in their exile, or in their death. But why do I talk of dazzling or blazing? it was then that they did good, that they gave light, and that they became guides to mankind. Thofe aims alone are worthy of fpirits truly great, and fuch I therefore hope will be yours. Refentment indeed may remain, perhaps cannot be quite extinguifhed, in the nobleft minds; but revenge will never harbour there: Higher principles than thofe of the firft, and better principles than thofe of the latter, will infallibly influence men whofe thoughts and whofe hearts are enlarged, and caufe them to prefer the whole to any part of mankind, efpecially to fo fmall a part as one's fingle felf. Believe me, my Lord, I look upon you as a fpirit entered into another life, as one juft upon the edge of immortality, where the paffions and affections muft be much more exalted, and where you ought to defpife all little views and all mean retrofpects. Nothing is worth your looking back: and therefore look forward, and make (as you can) the world look after you; but take care it be not with pity, but with efteem and admiration. I am, with the greateft fincerity and paffion for your fame as well as happinefs, your, &c.

The above moft charming and moft affectionate letter was written about a month before Atterbury bifhop of Rochefter was fent into banifhment, and is univerfally admired.

STENTOROPHONIC TUBE, a fpeaking trumpet; thus called from Stentor, a perfon mentioned by Homer. See TRUMPET.

STEP, in a fhip, a block of wood fixed on the decks or bottom of a fhip, and having a hole in its upper fide, fitted to receive the heel of a maft or capftern. The fteps of the main and foremafts of every fhip reft upon the kelfon, to which they are firmly fecured by knees, bolts, or fpike-nails. The ftep of the mizen-maft ufually refts upon the lower deck.

STEPHANIUM, a genus of plants belonging to the pentandria clafs; and in the natural method ranking under the 47th order, *Stellatæ*. See BOTANY *Index*.

STEPHANOPHORUS, in antiquity, the chief prieft of Pallas, who prefided over the reft. It was ufual for every god to have a chief prieft; that of Pallas was the Stephanophorus juft mentioned, and that of Hercules was called Dadouchus.—Stephanophorus was alfo a prieft who affifted the women in the celebration of the feftival Thefmophoria.

STEPHANUS BYZANTINUS, an able grammarian, who lived in the fifth or fixth century. He wrote a Dictionary, in which he made a great number of obfervations, borrowed from mythology and hiftory, which fhowed the origin of cities and colonies, of which we have nothing remaining but a mean abridgement by Hermolaus the grammarian; but from that work the learned have received great light; and Sigonius, Cafaubon, Scaliger, Salmafius, &c. have employed themfelves in illuftrating it.

STEPHEN, king of England. See ENGLAND, N° 108, &c.

STEPHEN, or *St Stephen's Day*, a feftival of the Chriftian church, obferved on the 26th of December, in memory of the firft martyr St Stephen.

STEPHENS, a family of printers defervedly celebrated. They flourifhed at the time of the revival of learning, and contributed a great deal towards difpelling the cloud of ignorance which had fo long overfhadowed Europe. Some of the claffics before the 16th century were in a great meafure loft, and all of them were exceedingly corrupted. By their abilities and indefatigable induftry thefe defects were fupplied, and the learned were furnifhed with beautiful and correct editions of the Greek and Roman authors. Thus the world was not only fupplied with an inexhauftible fund of amufement and inftruction in thefe ancient writings; but it is to the ardour which they infpired, and to the model of elegance which they difplayed, that the prefent advanced ftate of literature is in a great meafure owing.

HENRY STEPHENS, the firft of thefe illuftrious men, was born in France, foon after the difcovery of printing, perhaps about the year 1465. He fettled as a printer at Paris, and was probably patronized by Louis XII. A great proportion of the books which he publifhed were Latin: They are printed in the Roman letter, and are not inelegant, though fome of them abound rather too much in contractions. He died about the year 1520, and left behind him three fons, Francis, Robert, and Charles. His widow married Simeon de Colines (*Colinæus* in Latin), who thus got poffeffion of Henry's printing-houfe, and continued the profeffion till his death.

Of FRANCIS, the eldeft fon, little more is known than that he carried on bufinefs along with his father-in-law Colinæus, and that he died at Paris in 1550.

ROBERT STEPHENS, the fecond fon, was born in 1503. In his youth he made great proficiency in the Roman, Greek, and Hebrew languages, and at the age of 19 had acquired fo much knowledge, that his father-in-law entrufted him with the management of his prefs. An edition of the New Teftament was publifhed under his infpection, which gave great offence to the Paris divines, who accufed him of herefy, and threatened to prevent the fale of the book. Soon after he began bufinefs himfelf, and married Perrete the daughter of Jodocus Badius, a printer and an author. She was a woman of learning, and underftood Latin, which indeed was the neceffary confequence of her fituation. Her hufband always entertained a number of learned men as correctors of the prefs: Being foreigners, and of different nations, they made ufe of no other language but Latin; which Perrete being accuftomed to hear, was able in a fhort time

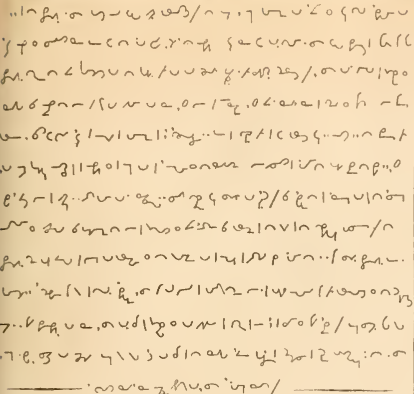
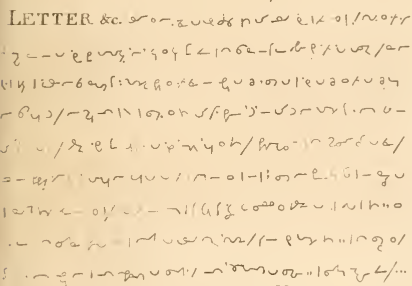
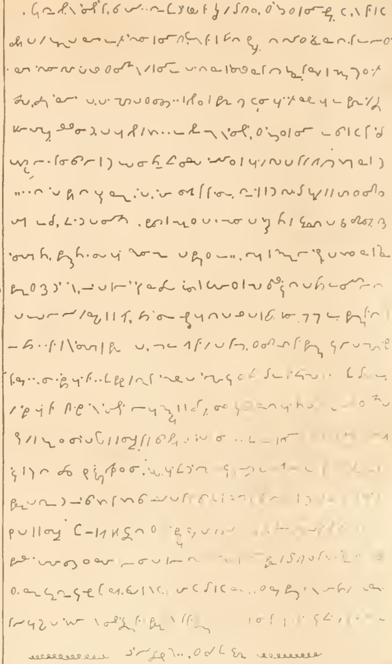
FABRICIUS' Reply to PYRRHUS.



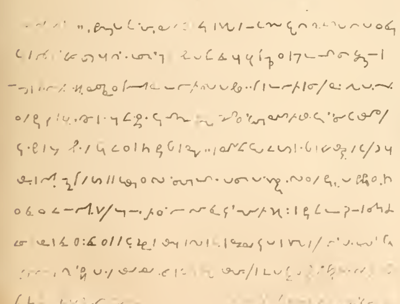
LETTER &c.

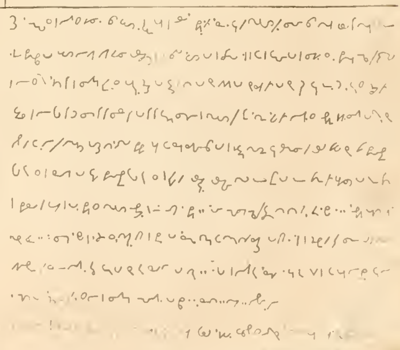


St PAUL'S SPEECH.



POPE to ATTERBURY.





Stephens. not only to underſtand, but even to ſpeak with tolerable eaſe.

In 1531 he publiſhed his Latin "Theſaurus;" a work of great importance, which he laboured at for two years. The mark which he put upon all his books was a tree branched, with a man looking upon it, and theſe words *noli altum ſapere*, to which he ſometimes added *ſed time*. In 1539, Francis I. made him his printer, and ordered a new ſet of elegant types to be founded for him. His frequent editions of the New Teſtament gave great offence to the doctors of the Sorbonne, who accuſed him of hereſy for his annotations, and infiſted upon the ſuppreſſion of ſome of his books. Although Henry the French king in ſome meaſure protected him, the perſecution of theſe divines rendered him ſo unhappy, not to mention the expence and loſs of time which an almoſt conſtant attendance at court unavoidably occaſioned, that in 1552 he abandoned his country and went to Geneva. Here he embraced the Proteſtant religion, and thus juſtified in ſome meaſure the ſuſpicions of his theological enemies. It has been affirmed by ſeveral writers that he carried along with him the royal types, and the moulds alſo in which they were caſt; but it is certain that he never afterwards made uſe of thoſe types. Beſides, is it poſſible that the author of ſo daring a theft could have been not only protected in Geneva, but even courted and honoured by the moſt eminent men of the age? Is it credible that ſuch a crime could have been concealed for 60 years; or that Henry, the ſon and heir of the perpetrator, would have enjoyed the favour of the French king, if Robert Stephens had acted ſuch a ſhameful part? If he was burnt in effigy at Paris, it was not for theft, but for having changed his religion. After his arrival at Geneva, he publiſhed an account of the diſpute between him and the Paris divines, which does as much honour to his abilities as his *Theſaurus* does to his learning. He died in 1559, after a life of the moſt extraordinary induſtry. The books of which he was the editor were not fewer than 360. Many of them were ancient claſſics in different languages. Several were accompanied with annotations which he collected, and all of them were corrected by collating manuſcripts. He was ſo anxious to obtain perfect accuracy, that he uſed to expoſe his proofs in public, and reward thoſe who diſcovered a miſtake. His books conſequently were very correct. It is ſaid that his New Teſtament, called *O Mirificam* (becauſe the preface begins with theſe words), has not a ſingle fault.

It was Robert Stephens who firſt divided the New Teſtament into verſes during a journey between Paris and Lyons. The advantages of this improvement are fully counterbalanced by its defects. It has deſtroyed the unity of the books, and induced many commentators to conſider every verſe as a diſtinct and independent aphoriſm. To this in ſome meaſure is to be aſcribed the many abſurd interpretations and creeds that have been forced out of that book.

By his laſt will his eſtate was left excluſively to ſuch of his children as ſhould ſettle at Geneva. He left behind him three ſons, Henry, Robert, and Francis.

Charles Stephens, the third ſon of Henry, was, like the reſt of his family, familiarly acquainted with the learned languages. This recommended him to Lazarus de Baif, who made him tutor to his ſon, and in 1540 carried him along with him to Germany. He ſtudied medicine, and practiſed it with ſucceſs in France. He did not, however, forſake the profeſſion of his family, but exerciſed it in Paris, where he became the editor of many books remarkable for neatneſs and elegance. He wrote above thirty treatiſes on different ſubjects, particularly on botany, anatomy, and hiſtory. He died in 1564.

Robert Stephens, the ſon of Robert the firſt of that name, did not accompany his father to Geneva, but continued to profeſs the Catholic religion, and to reſide at Paris. His letter was remarkably beautiful.—He was made king's printer, and died about 1589.

His brother Francis was alſo a printer. He embraced the Proteſtant religion, and reſided at Geneva.

Henry Stephens, the remaining ſon of Robert, was born at Paris in 1528. He became the moſt learned and moſt celebrated of all his family. From his very birth almoſt he gave proofs of uncommon abilities, and diſplayed an ardent paſſion for knowledge. The Medea of Euripides, which he ſaw acted while at ſchool, firſt kindled his love for poetry, and inſpired him with the deſire of acquiring the language in which that tragedy is written. He intreated his father not to condemn him to ſtudy Latin, which he already underſtood from converſation, but to initiate him at once into the knowledge of Greek. His father willingly granted his requeſt; and Henry applied with ſuch vigour, that in a ſhort time he could repeat the Medea by heart. He afterwards ſtudied Greek under Peter Daneſius, who was tutor to the Dauphin, and finally heard the lectures of Tuſanus and Turnebus. He became eager at an early age to underſtand aſtrology, and accordingly attended a profeſſor of that myſterious art; but he was not long in diſcovering its abſurdity. At 19 he began his travels, which he undertook in order to examine foreign libraries, and to become acquainted with learned men. He ſpent two years in Italy, and returned into France completely maſter of Italian, and bringing along with him copies of ſeveral ſcarce authors, particularly a part of Anacreon, which before was thought loſt.

He found his father publiſhing an edition of the New Teſtament, to which he prefixed ſome Greek verſes.—Soon after, he viſited England and the Netherlands, where he met with John Clement, an Engliſhman, to whom he was indebted for the remaining odes of Anacreon. During this journey he learned the Spaniſh language, which was very much ſpoken at that time in the Low Countries.

Whether Henry accompanied his father to Geneva or not is uncertain; at leaſt he muſt have returned immediately to France, for we find him ſoon after eſtabliſhed at Paris, and publiſhing the odes of Anacreon. In 1554 he went to Rome, and thence to Naples. This journey was undertaken at the requeſt, and in the ſervice, of the French government. He was diſcovered, and would have been arreſted as a ſpy, had he not by his addreſs and ſkill in the language of the country been able to paſs himſelf for a native of Italy. On his return to France he aſſumed the title of printer to Ulric Fugger, a very rich and learned German nobleman, who allowed him a conſiderable penſion.

In 1560 he married a relation, as is generally ſuppoſed, of Henry Scrimgeour, a Scotch nobleman, with whom he was intimately acquainted. She was a woman, as he himſelf informs us, endowed with the nobleſt ſpirit

Stephens.

spirit and the most amiable dispositions. Her death, which happened in 1586, brought on a disease that had twice attacked him before. It was a disgust at all those pursuits which had formerly charmed him, an aversion to reading and the sight of books. It was probably occasioned by too constant and severe an application to literary pursuits. In 1572 he published his *Thesaurus Linguæ Græcæ*, one of the greatest works, perhaps, that ever was executed by one man, if we consider the wretched materials which more ancient dictionaries could furnish, if we consider the size and perfection of the work, and the immense labour and learning which must have been employed in the compilation. This work had been carried on at a greater expence than he could well bear. He expected to be reimbursed by the sale of the book, but he was unfortunately disappointed. John Scapula, one of his own servants, extracted from it whatever he thought would be most serviceable to students, and published it beforehand in 4th. By this act of treachery Henry was reduced to poverty.

See *Scapula*.

About this time he was much beloved by Henry III. of France, who treated him so kindly, and made him such flattering promises, that he resided frequently at court. But these promises were never fulfilled, owing to the civil wars which soon after distracted France, and the unfortunate death of King Henry himself. During the remainder of his life his situation was very unsettled. We find him sometimes at Paris, sometimes in Geneva, in Germany, and even in Hungary. He died at Lyons in 1598, at the age of 70. He was fond of poetry from his very infancy. It was a custom of his to compose verses on horseback, and even to write them, though he generally rode a very mettlesome steed. His *Thesaurus* was his great work, but he was also the author of several other treatises. His poems are numerous: His Apology for Herodotus is a witty satire on the Roman Catholics. His Concordance to the New Testament must have been a laborious work, and has deservedly endeared him to every Christian who wishes to acquire a rational and critical knowledge of the Scriptures. The number of books which he published, though fewer than his father, was great, and superior in elegance to any thing which the world had then seen. A great proportion of them were Greek; he was the editor, however, of many Roman and even of some eastern writings. His Greek classics are remarkably correct; the principal of them are Homer, Anacreon, Æschylus, Maximus Tyrius, Diodorus Siculus, Pindar, Xenophon, Thucydides, Herodotus, Sophocles, Diogenes Laertius, Plutarch, Plato, Apollonius Rhodius, Æschines, Lysias, Callimachus, Theocritus, Herodian, Dionysius Hallicarnassensis, Dion Cassius, Isocrates, Appian, Xiphilin, &c. His temper in the latter part of his life is represented as haughty and severe, owing probably to his disappointments. He left behind him a son and two daughters, one of whom was married to the learned Isaac Casaubon.

Paul Stephens, the son of Henry, continued his father's profession at Geneva. He was a man of learning, and wrote translations of several books, and published a considerable number of the ancient classics; but his editions possess little of his father's elegance. He died in 1627, at the age of 60, after selling his types to one Chouet a printer.—His son Antony, the last printer of the family, abandoned the Protestant religion, and returned to France, the country of his ancestors. He received letters of naturalization in 1612, and was made printer to the king; but managing his affairs ill, he was reduced to poverty, and obliged to retire into an hospital, where he died in 1674, miserable and blind, at the age of 80.

Stephens ‖ Stereometer.

STERCORARIANS, or Stercoranistæ, formed from *stercus* "dung," a name which those of the Romish church anciently gave to such as held that the host was liable to digestion, and all its consequences, like other food.

STERCULIA, a genus of plants belonging to the class monœcia; and in the natural system ranging under the 38th order, *tricoccæ*. See Botany *Index*.

STEREOGRAPHIC projection, is the projection of the circles of the sphere on the plane of some one great circle, the eye being placed in the pole of that circle. See *Projection of the Sphere*.

STEREOMETER, an instrument invented in France for measuring the volume of a body, however irregular, without plunging it in any liquid. If the volume of air contained in a vessel be measured, when the vessel contains air only, and also when it contains a body whose volume is required to be known, the volume of air ascertained by the first measurement, deducting the volume ascertained by the second, will be the volume of the body itself. Again, if the volume of any mass of air be inversely as the pressure to which it is subjected, the temperature being supposed constant, it will be easy to deduce, from the mathematical relations of quantity, the whole bulk if the difference between the two bulks under two known pressures be obtained by experiment.

Suppose that the first pressure is double the second, or the second volume of air double the first, and the difference equal to 50 cubic inches; the first volume of air will likewise be 50 cubic inches. The design of the stereometer is to ascertain this difference at two known pressures.

The instrument is a kind of funnel AB (fig. 1.) composed of a capsule A, in which the body is placed, and the tube B as uniform in the bore as can be procured. The upper edge of the capsule is ground with emery, that it may be hermetically closed with a glass cover M slightly greased. A double scale is pasted on the tube, having two sets of graduations; one to denote the length, and the other the capacities, as determined by experiment.

Plate DIX. Fig. 1.

When this instrument is used, it must be plunged into a vessel of mercury, with the tube very upright, till the mercury rise within and without to a point C of the scale. See fig. 2.

Fig. 2.

The capsule is then closed with the cover, which being greased will prevent its communication between the external air and that contained within the capsule and tube.

In this situation of the instrument, the internal air is compressed by the weight of the atmosphere, expressed by the length of the mercury in the tube of the common barometer.

The instrument is then elevated, still keeping the tube in the vertical position. It is thus represented, fig. 2. second position. The mercury descends in the tube, but not to the level of the external surface, and a column of mercury DE remains suspended in the tube, the height of which is known by the scale. The interior air is less compressed

Fig. 1.

Fig. 2.

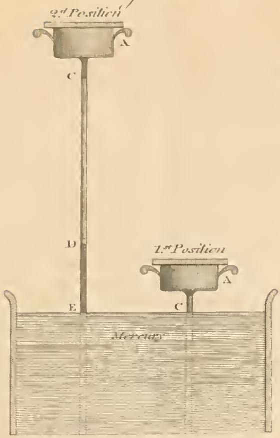


Fig. 3.

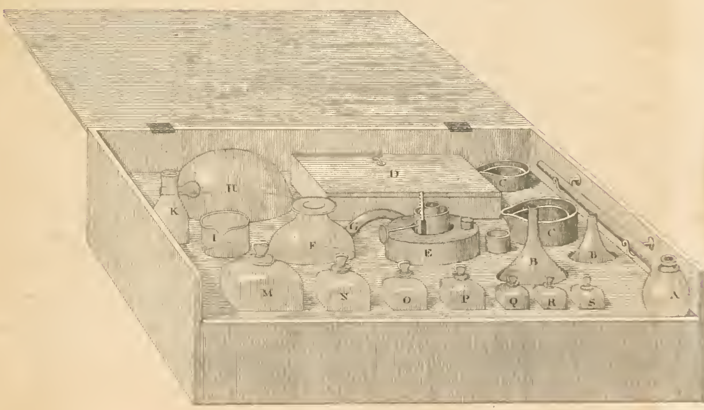
SOILS Analysis of.



W. Train Sculpt.

compreffed than before, the increafe of its volume being equal to the whole capacity of the tube from C to D, indicated by the fecond fcale.

It is therefore known that the preffures are in proportion to the barometrical column, and to the fame column —DE. The bulks of the air in thefe two ftates are inverfely in the fame proportion; and the difference between thefe bulks is the abfolute quantity left void in the tube by the fall of the mercury; from which data the following rule is deduced. Multiply the number expreffing the lefs preffure by that which denotes the augmentation of capacity, and divide the product by the number which denotes the difference of the preffures. The quotient is the bulk of the air when fubject to the greater preffure.

Suppofe the height of the mercury in the barometer to be 78 centimetres, and the inftrument being empty to be plunged into the mercury to the point C. It is then covered and raifed till the fmall column of mercury DE is fufpended, fay at the height of fix centimetres. The internal air at firft compreffed by a force reprefented by 78 centimetres, is now only compreffed by a force $= 72$ centimetres, or $78 - 6 = 72$.

Suppofe that the capacity of the part CD of the tube which the mercury has quitted is two cubic centimetres.

Then $\frac{72}{6} \times 2 = 24$ cubical centimetres, the volume of the air included in the inftrument when the mercury rofe as high as C in the tube.

The body of which the volume is to be afcertained muft then be placed in the capfule, and the operation repeated. Let the column of mercury fufpended be $=8$ centimetres, when the capacity of the part CD of the tube is $=2$ centimetres cubic. Then the greateft preffure being denoted by 78 centimetres, the leaft will be 70 centimetres, the difference of preffure being 8, and difference of the volumes two cubic centimetres.

Hence $\frac{70}{8} \times 2$ gives the bulk of the included air under the greateft preffure 17.5 cubic centimetres. Then $24 - 17.5 = 6.5$ the volume of the body introduced. If the abfolute weight of the body be multiplied by its bulk in centimetres, and divided by the abfolute weight of one cubic centimetre of diftilled water, the quotient will be $=$ the fpecific gravity of the body in the common form of the tables, where diftilled water is taken as unity, or the term of comparifon.

Mr Nicholfon fuppofes that the author of the invention had not finifhed his meditations on the fubject. If he had, it is probable that he would have determined his preffures, as well as the meafures of bulks, by weight. For if the whole inftrument were fet to its pofitions by
Fig. 3. fufpending it from one arm of a balance at H (fig. 3.) the quantity of counterpoife, when in equilibrio, might be applied to determine the preffures to a degree of accuracy much greater than can be obtained by linear meafurement.

STEREOMETRY, Στερεομετρια, formed of στερεος *folid*, and μετρον *meafure*, that part of geometry which teaches how to meafure folid bodies, i. e. to find the folidity or folid contents of bodies; as globes, cylinders, cubes, veffels, fhips, &c.

STEREOTOMY, formed from στερεος, and τομη, *fection*, the art or act of cutting folids, or making fections thereof; as walls and other membranes in the profiles of architecture.

STEREOTYPE PRINTING, a method of printing, which was introduced into this country by William Ged of Edinburgh before the middle of the 18th century, and which has been revived of late, and greatly improved by the French. It has alfo been brought into practice in Britain by Earl Stanhope, who has produced fome beautiful fpecimens of it. Some perfons feem difpofed to difpute the invention of Ged, feeing that the fame method of printing by wooden blocks was practifed by the Chinefe and Japanefe many hundred years ago. See GED, *life of*, and PRINTING.

STERILITY, barrennefs, in oppofition to fertility. It has been afferted by many authors, that all monfters produced by a mixture of different fpecies of animals, fuch as mules, are barren; but this does not hold univerfally, even with the mule, which is the inftance moft generally adduced.

Sterility in women fometimes happens from a mifcarriage, or violent labour injuring fome of the genital parts; but one of the moft frequent caufes is the fuppreffion of the menftrual flux.—There are other caufes arifing from various difeafes incident to thofe parts, by which the uterus may be unfit to receive or retain the male feed;—from the tubæ fallopianæ being too fhort, or having loft their erective power; in either of which cafes no conception can take place;—from univerfal debility and relaxation; or a local debility of the genital fyftem; by which means, the parts having loft their tone or contractile power, the femen is thrown off immediately *poft coitum*;—from imperforation of the vagina, the uterus, or the *tubæ*, or from difeafed ova, &c. Hence medical treatment can only avail in cafes arifing from topical or univerfal debility; in correcting irregularities of the menftrual flux, or in removing tumors, cicatrices, or conftrictions of the paffage, by the art of furgery.

STERIS, a genus of plants belonging to the clafs pentandria. See BOTANY *Index*.

STERLING, an epithet by which genuine Englifh money is diftinguifhed. It is unneceffary to mention the various conjecturies of antiquaries about the origin and meaning of this appellation. The moft probable opinion feems to be this, that fome artifts from Germany, who were called *Efterlings*, from the fituation of their country, had been employed in fabricating our money, which confifted chiefly of filver pennies; and that from them the penny was called an *efterling*, and our money *efterling* or *fterling* money. *Henry's Hiftory of Great Britain*, vol. ii. p. 541.

STERN, the pofterior face of a fhip; or that part which is reprefented to the view of a fpectator, placed on the continuation of the keel behind. The ftern is terminated above by the taffarel, and below by the counters; it is limited on the fides by the quarter-pieces, and the intermediate fpace comprehends the galleries and windows of the different cabins. See QUARTER *of a Ship*, SHIP, and SHIP-BUILDING.

STERN-Faft, a rope ufed to confine the ftern of a fhip or boat to any wharf or jetty head, &c.

STERN-Moft, in fea language, ufually denotes that part of a fleet of fhips which is in the rear, or fartheft a-ftern, as oppofed to head-moft.

STERN-Poſt, a long ſtraight piece of timber erected on the extremity of the keel, to ſuſtain the rudder and terminate the ſhip behind.

This piece ought to be well ſecured and ſupported; becauſe the ends of all the lower planks of the ſhip's bottom are fixed in a channel, cut on its ſurface; and the whole weight of the rudder is ſuſtained by it.

STERN-Sheets, that part of a boat which is contained between the ſtern and the aſtmoſt or hindmoſt ſeat of the rowers. It is generally furniſhed with benches to accommodate the paſſengers. See BOAT.

STERNA, the TERN; a genus of birds arranged under the order of *palmipedes*. See ORNITHOLOGY *Index*.

STERNE, LAURENCE, an Engliſh writer of a very peculiar caſt, was born at Clomwell, in the ſouth of Ireland, on 24th November 1713. His father Roger Sterne was the grandſon of Sterne archbiſhop of York, who has been ſuppoſed, we know not upon what grounds, to have been the author of the excellent book entitled "The Whole Duty of Man." Laurence inherited nothing of his anceſtor's manner of writing, but rather reſembled Rabelais, whoſe wit he carried with him even into the pulpit.

In 1722 he was ſent to ſchool at Halifax in Yorkſhire, where he continued till 1732, when he was removed to Jeſus College in Cambridge. How long he reſided in college, or what progreſs he made in literature or ſcience, is not known: his works diſplay rather native genius than profound erudition. Upon quitting the univerſity he went to York, and being in orders was preſented to the living of Sutton by the intereſt of his uncle Dr Sterne, a prebendary of that church. In 1741 he married, and was ſoon afterwards made a prebendary of York, by the intereſt alſo of his uncle, who was then upon very good terms with him; but "quickly quarrelled with him (he ſays), and became his bittereſt enemy, becauſe he would not be a party man, and write paragraphs in the newſpapers." By his wife's means he got the living of Stillington, but remained near 20 years at Sutton, doing duty at both places. He was then in very good health, which, however, ſoon after forſook him; and books, painting, fiddling, and ſhooting, were, as he tells us, his amuſements.

In 1760, he went to London to publiſh his two firſt volumes of "Triſtram Shandy;" and was that year preſented to the curacy of Coxwold. In 1762 he went to France, and two years after to Italy, for the recovery of his health; but his health never was recovered. He languiſhed under a conſumption of the lungs, without the ſlighteſt depreſſion of ſpirits, till 1768, when death put a period to his terreſtrial exiſtence.

The works of Sterne are very generally read. They conſiſt of, 1. The Life and Opinions of Triſtram Shandy; 2. Sermons; 3. A Sentimental Journey; 4. Letters, publiſhed ſince his death. In every ſerious page, and in many of much levity, the author writes in praiſe of benevolence, and declares that no one who knew him could ſuppoſe him one of thoſe wretches who heap miſfortune upon misfortune: But we have heard anecdotes of him extremely well authenticated, which proved that it was eaſier for him to praiſe this virtue than to practiſe it. His wit is univerſally allowed; but many readers have perſuaded themſelves that they found wit in his blank pages, while it is probable that he intended nothing but to amuſe himſelf with the idea of the ſage conjectures to which theſe pages would give occaſion. Even his originality is not ſuch as is generally ſuppoſed by thoſe fond admirers of the Shandean manner, who have preſumed to compare him with Swift, Arbuthnot, and Butler. He has borrowed both matter and manner from various authors, and in particular from an old work, "The Anatomy of Melancholy by Burton," as every reader may be convinced by the learned, elegant, and candid comments on his works publiſhed by Dr Ferriar, in the fourth volume of the Memoirs of the Literary and Philoſophical Society of Mancheſter.

STERNOCOSTALES, commonly called the *muſculi triangulares ſterni*, in *Anatomy*, are five pairs of fleſhy planes, diſpoſed more or leſs obliquely on each ſide the ſternum, on the inſides of the cartilages of the ſecond, third, fourth, fifth, and ſixth true ribs.

STERNO-HYOIDÆUS, in *Anatomy*. See *Table of the Muſcles*, under the article ANATOMY.

STERNOMANTIS, in antiquity, a deſignation given to the Delphian prieſteſs, more uſually called PYTHIA.—Sternomantis is alſo uſed for any one that had a propheſying demon within him.

STERNOMASTOIDÆUS, a muſcle. See *Table of the Muſcles*, under ANATOMY.

STERNOTHYROIDEUS, a muſcle. See *Table of the Muſcles*, under ANATOMY.

STERNUM. See ANATOMY *Index*.

STERNUTATIVE, or STERNUTATORY, a medicine proper to produce ſneezing. See SNEEZING.

STETIN, or STETTIN, a ſea-port town of Germany, in the circle of Upper Saxony, and capital of Hither Pomerania, with the title of a duchy, and a caſtle. It had long a famous ſchool, which the wars of Germany never diſturbed. The ancient dukes of Pomerania reſided here; and it was taken by the elector of Brandenburg in 1676, but given to Sweden by the treaty of Nimeguen. In 1713 it ſubmitted to the allies; and then the ſaid elector was put in poſſeſſion again of this important place, which is a bulwark to the marche of Brandenburg; and the fortifications have been greatly improved. It is now a flouriſhing place, and carries on a conſiderable trade. It is ſeated on the river Oder, 72 miles north of Francfort, and 70 north by eaſt of Berlin. E. Long. 14. 38. N. Lat. 53. 35. The duchy is 125 miles in length, and borders upon Mecklenburg, and partly upon Brandenburg. The breadth is from 17 to 25 miles, and it is divided by the river Oder into two parts.

STEW, a ſmall kind of fiſh-pond, the peculiar uſe of which is to maintain fiſh, and keep them in readineſs for the daily uſe of the family, &c.

STEWS (from the French *eſtuves*, i. e. *thermæ*, *balneum*), thoſe places which were permitted in England to women of profeſſed incontinency; ſo called, becauſe diſſolute perſons are wont to prepare themſelves for venereous acts by bathing; and hot baths were by Homer reckoned among the effeminate ſort of pleaſures. Theſe ſtews were ſuppreſſed by King Henry VIII. about the year 1546.

STEWARD (*ſeneſcallus*, compounded of the Saxon *ſteda*, i. e. "room" or "ſtead," and *weard*, "a ward" or "keeper"), an officer appointed in another's ſtead or place, and always taken for a principal officer within his juriſdiction.

Steward. jurifdiction. Of thefe there are various kinds. The greateft officer under the crown is the lord high-fteward of England, an office that was anciently the inheritance of the earls of Leicefter, till forfeited by Simon de Mountfort to King Henry III. But the power of this officer is fo very great, that it has not been judged fafe to truft it any longer in the hands of a fubject, excepting only *pro hac vice*, occafionally: as to officiate at a coronation, at the arraignment of a nobleman for high-treafon, or the like. During his office, the fteward bears a white ftaff in his hand; and the trial, &c. ended, he breaks the ftaff, and with it his commiffion expires. There is likewife a lord-fteward of the king's houfehold, who is the chief officer of the king's court, has the care of the king's houfe, and authority over all the officers and fervants of the houfehold, except fuch as belong to the chapel, chamber, and ftable.

Steward, an officer in a fhip of war, appointed by the purfer to diftribute the different fpecies of provifions to the officers and crew; for which purpofe he is furnifhed with a mate and proper affiftants.

Court of the Lord High Steward of Great Britain, is a court inftituted for the trial of peers indicted for treafon or felony, or for mifprifion of either. The office of this great magiftrate is very ancient, and was formerly hereditary, or at leaft held for life, or *dum bene fe gefferit:* but now it is ufually, and hath been for many centuries paft, granted *pro hac vice* only; and it hath been the conftant practice (and therefore feems now to have become neceffary) to grant it to a lord of parliament, elfe he is incapable to dry fuch delinquent peer. When fuch an indictment is therefore found by a grand jury of freeholders in the King's bench, or at the affizes before the juftices of *oyer* and *terminer*, it is to be removed by a writ of *certiorari* into the court of the lord high-fteward, which has the only power to determine it. A peer may plead a pardon before the court of King's-bench, and the judges have power to allow it, in order to prevent the trouble of appointing an high-fteward merely for the purpofe of receiving fuch plea: but he may not plead in that inferior court any other plea, as guilty or not guilty of the indictment, but only in this court; becaufe, in confequence of fuch plea, it is poffible that judgement of death might be awarded againft him. The king, therefore, in cafe a peer be indicted of treafon, felony, or mifprifion, creates a lord high-fteward *pro hac vice* by commiffion under the great feal; which recites the indictment fo found, and gives his Grace power to receive and try it *fecundum legem et confuetudinem Angliæ*. Then when the indictment is regularly removed by writ of *certiorari*, commanding the inferior court to certify it up to him, the lord high-fteward directs a precept to a ferjeant at arms, to fummon the lords to attend and try the indicted peer. This precept was formerly iffued to fummon only 18 or 20 felected from the body of the peers; then the number came to be indefinite; and the cuftom was for the lord-high-fteward to fummon as many as he thought proper (but of late years not lefs than 23); and that thofe lords only fhould fit upon the trial; which threw a monftrous weight of power into the hands of the crown, and this its great officer, of felecting only fuch peers as the then predominant party fhould moft approve of. And accordingly, when the earl of Clarendon fell into difgrace with Charles II. there was a defign formed to prorogue the parliament, in order to try him by a felect number of peers; it being doubted whether the whole houfe could be induced to fall in with the views of the court. But now, by ftatute 7 W. III. c. 3. upon all trials of peers for treafon or mifprifion, all the peers who have a right to fit and vote in parliament fhall be fummoned at leaft 20 days before fuch trial, to appear and vote therein; and every lord appearing fhall vote in the trial of fuch peer, firft taking the oaths of allegiance and fupremacy, and fubfcribing the declaration againft popery.

Blackft. Comment. vol. iv.

During the feffion of parliament, the trial of an indicted peer is not properly in the court of the lord high-fteward, but before the court laft mentioned of our lord the king in parliament. It is true, a lord high-fteward is always appointed in that cafe to regulate and add weight to the proceedings: but he is rather in the nature of a fpeaker *pro tempore*, or chairman of the court, than the judge of it; for the collective body of the peers are therein the judges both of law and fact, and the high-fteward has a vote with the reft in right of his peerage. But in the court of the lord high-fteward, which is held in the recefs of parliament, he is the fole judge of matters of law, as the lords triors are in matters of fact; and as they may not interfere with him in regulating the proceedings of the court, fo he has no right to intermix with them in giving any vote upon the trial. Therefore, upon the conviction and attainder of a peer for murder in full parliament, it hath been holden by the judges, that in cafe the day appointed in the judgement for execution fhould lapfe before execution done, a new time of execution may be appointed by either the high court of parliament during its fitting, though no high-fteward be exifting, or, in the recefs of parliament, by the court of King's-bench, the record being removed into that court.

It has been a point of fome controverfy, whether the bifhops have now a right to fit in the court of the lord-high-fteward to try indictments of treafon and mifprifion. Some incline to imagine them included under the general words of the ftatute of King William "all peers who have a right to fit and vote in parliament;" but the expreffion had been much clearer, if it had been "all lords," and not "all peers;" for though bifhops, on account of the baronies annexed to their bifhoprics, are clearly lords of parliament, yet their blood not being ennobled, they are not univerfally allowed to be peers with the temporal nobility: and perhaps this word might be inferted purpofely with a view to exclude them. However, there is no inftance of their fitting on trials for capital offences, even upon impeachments or indictments in full parliament, much lefs in the court we are now treating of; for indeed they ufually withdraw voluntarily, but enter a proteft, declaring their right to ftay. It is obfervable, that in the 11th chapter of the conftitutions of Clarendon, made in parliament 11th Henry II. they are exprefsly excufed, rather than excluded, from fitting and voting in trials, which concern life or limb: *epifcopi, ficut cæteri barones, debent intereffe judiciis cum baronibus, quoufque perveniatur ad diminutionem membrorum vel ad mortem.* And Becket's quarrel with the king hereupon was not on account of the exception (which was agreeable to the canon law), but of the general rule, that compelled the bifhops to attend at all. And the determination of the houfe of lords

lords in the earl of Danby's cafe, which hath ever fince been adhered to, is confonant to thefe conftitutions; "that the lords fpiritual have a right to ftay and fit in court in capital cafes, till the court proceeds to the vote of guilty or not guilty." It muft be noted, that this refolution extends only to trials in full parliament; for to the court of the lord high-fteward (in which no vote can be given, but merely that of guilty or not guilty), no bifhop, as fuch, ever was or could be fummoned: and though the ftatute of King William regulates the proceedings in that court, as well as in the court of parliament, yet it never intended to new-model or alter its conftitution; and confequently does not give the lords fpiritual any right, in cafes of blood, which they had not before. And what makes their exclufion more reafonable is, that they have no right to be tried themfelves in the court of the lord high-fteward, and therefore furely ought not to be judges there. For the privilege of being thus tried depends upon nobility of blood rather than a feat in the houfe, as appears from the trials of the popifh lords, of lords under age, and (fince the union) of the Scotch nobility, though not in the number of the fixteen; and from the trials of females, fuch as the queen confort or dowager, and of all peereffes by birth; and peereffes by marriage alfo, unlefs they have, when dowagers, difparaged themfelves by taking a commoner to their fecond hufband.

STEWARD of the Chiltern Hundreds. See *CHILTERN Hundreds.*

STEWART, DR MATTHEW, an eminent mathematician, was in 1717 born at Rothfay in the ifle of Bute, of which parifh his father was minifter. Being intended for the church, he went through the ufual courfe of a grammar-fchool education, and was in 1734 received as a ftudent into the univerfity of Glafgow. There he had the happinefs of having for his preceptors in moral fcience and in mathematics the celebrated profeffors Hutchefon and Simfon; by the latter of whom he was inftructed in what may not improperly be called the *arcana* of the ancient geometry.

Account of Dr Stewart in the Edinburgh Philofophical Tranfactions, vol. i. by Mr Playfair.

Mr Stewart's views making it neceffary for him to remove to Edinburgh, he was introduced by Dr Simfon to Mr Maclaurin, that his mathematical ftudies might fuffer no interruption; and he attended the lectures of that great mafter with fuch advantage as might be expected from eminent abilities, directed by the judgement of him who made the philofophy and geometry of Newton intelligible to ordinary capacities. Mr Stewart, however, had acquired, from his intimacy with Dr Simfon, fuch a predilection for the ancient geometry, as the modern analyfis, however powerfully recommended, could not leffen; and he kept up a regular correfpondence with his old mafter, giving him an account of his progrefs and his difcoveries in geometry, and receiving in return many curious communications refpecting the *Loci Plani* and the porifms of Euclid. See PORISM and SIMSON.

While the fecond invention of porifms, to which more genius was perhaps required than to the firft difcovery of them, employed Dr Simfon, Mr Stewart purfued the fame fubject in a different and new direction. In doing fo, he was led to the difcovery of thofe curious and interefting propofitions which were publifhed under the title of *General Theorems* in 1746. They were given without the demonftrations; but did not fail to place their difcoverer at once among the geometers of the firft rank. They are for the moft part porifms, though Mr Stewart, careful not to anticipate the difcoveries of his friend, gave them no other name than that of theorems.

Our author had before this period entered into the church; and obtained, through the patronage of the duke of Argyle and the earl of Bute, the living of Rofeneath, a retired country parifh in the weft of Scotland: but in 1747 he was elected to the mathematical chair in the univerfity of Edinburgh, which had become vacant the year before by the death of Mr Maclaurin. The duties of this office gave a turn fomewhat different to his purfuits, and led him to think of the moft fimple and elegant means of explaining thofe difficult propofitions which were hitherto only acceffible to men deeply verfed in the modern analyfis. In doing this, he was purfuing the object which of all others he moft ardently wifhed to attain, viz. the application of geometry to fuch problems as the algebraic calculus alone had been thought able to refolve. His folution of Kepler's problem was the firft fpecimen of this kind which he gave to the world; and it was impoffible to have produced one more to the credit of the method he followed, or of the abilities with which he applied it. On this problem the utmoft refources of the integral calculus had been employed. But though many excellent folutions had been given, there was none of them at once direct in its method and fimple in its principles. Mr Stewart was fo happy as to attain both thefe objects; and his folution appeared in the fecond volume of the Effays of the Philofophical Society of Edinburgh for the year 1756. In the firft volume of the fame collection there are fome other propofitions of Mr Stewart's, which are an extenfion of a curious theorem in the fourth book of Pappus. They have a relation to the fubject of porifms, and one of them forms the 91ft of Dr Simfon's Reftoration. They are befides very beautiful propofitions, and are demonftrated with all the elegance and fimplicity of the ancient analyfis.

The profecution of the plan which he had formed of introducing into the higher parts of mixed mathematics the ftrict and fimple form of ancient demonftration, produced the Tracts Phyfical and Mathematical, which were publifhed in 1761, and the Effay on the Sun's Diftance, which was publifhed in 1763. In this laft work it is acknowledged that he employed geometry on a tafk which geometry cannot perform; but while it is granted that his determination of the fun's diftance is by no means free from error, it may fafely be afferted that it contains a great deal which will always intereft geometers, and will always be admired by them. Few errors in fcience are redeemed by the difplay of fo much ingenuity, and what is more fingular, of fo much found reafoning. The inveftigation is everywhere elegant, and will probably be long regarded as a fpecimen of the moft arduous inquiry which has been attempted by mere geometry.

The Sun's Diftance was the laft work which Dr Stewart publifhed; and though he lived to fee feveral animadverfions on it made public, he declined entering into any controverfy. His difpofition was far from polemical; and he knew the value of that quiet which a literary man fhould rarely fuffer his antagonifts to interrupt. He ufed to fay, that the decifion of the point in in queſtion was now before the public; that if his inveſtigation was right it would never be overturned, and that if it was wrong it ought not to be defended. A few months before he publiſhed the eſſay juſt mentioned, he gave to the world another work, intitled *Propoſitiones Geometricæ More Veterum Demonſtratæ*. This title, it is ſaid, was given to it by Dr Simſon, who rejoiced in the publication of a work ſo well calculated to promote the ſtudy of the ancient geometry. It conſiſts of a ſeries of geometrical theorems for the moſt part new; inveſtigated firſt by an analyſis, and afterwards ſynthetically demonſtrated by the inverſion of the ſame analyſis.

Dr Stewart's conſtant uſe of the geometrical analyſis had put him in poſſeſſion of many valuable propoſitions which did not enter into the plan of any of the works that have been enumerated. Of theſe not a few have found a place in the writings of Dr Simſon, where they will for ever remain to mark the friendſhip of theſe two mathematicians, and to evince the eſteem which Dr Simſon entertained for the abilities of his pupil.

Soon after the publication of the Sun's Diſtance, Dr Stewart's health began to decline, and the duties of his office became burdenſome to him. In the year 1772 he retired to the country, where he afterwards ſpent the greater part of his life, and never reſumed his labours in the univerſity. But though mathematics had now ceaſed to be his buſineſs, they continued to be his amuſement till a very few years before his death, which happened on the 23d of January 1785, at the age of 68.

The habits of ſtudy, in a man of original genius, are objects of curioſity, and deſerve to be remembered. Concerning thoſe of Dr Stewart, his writings have made it unneceſſary to remark, that from his youth he had been accuſtomed to the moſt intenſe and continued application. In conſequence of this application, added to the natural vigour of his mind, he retained the memory of his diſcoveries in a manner that will hardly be believed. He rarely wrote down any of his inveſtigations till it became neceſſary to do ſo for the purpoſe of publication. When he diſcovered any propoſition, he would put down the enunciation with great accuracy, and on the ſame piece of paper would conſtruct very neatly the figure to which it referred. To theſe he truſted for recalling to his mind at any future period the demonſtration or the analyſis, however complicated it might be. Experience had taught him, that he might place this confidence in himſelf without any danger of diſappointment; and for this ſingular power he was probably more indebted to the activity of his invention than the mere tenacioufneſs of his memory. Though he was extremely ſtudious, he read few books, and verified the obſervation of M. D'Alembert, that of all the men of letters, mathematicians read leaſt of the writings of one another. His own inveſtigations occupied him ſufficiently; and indeed the world would have had reaſon to regret the miſapplication of his talents, had he employed in the mere acquiſition of knowledge that time which he could dedicate to works of invention.

STEWART, in *Scots Law*. See LAW *Index*.

STEWARTIA, a genus of plants belonging to the claſs monadelphia, and in the natural ſyſtem ranging under the 37th order, *Columniferæ*. See BOTANY *Index*.

STIBADIUM, among the Romans, a low kind of table couch or bed of a circular form, which ſucceeded to the triclinia, and was of different ſizes, according to the number of gueſts for which it was deſigned. Tables of this kind were called *hexaclina*, *octaclina*, or *enneaclina*, according as they held ſix, eight, or nine gueſts, and ſo of any other number.

STIBIUM, a name for ANTIMONY.

STICHOS, a name given by the old writers to a pectoral confection, the principal ingredient of which was the herb *marrubium* or horehound.

STICKLEBACK, a genus of fiſhes. See GASTEROSTEUS, ICHTHYOLOGY *Index*.

FOOT-STICKS, in *Printing*, ſlips of wood that lie between the foot of the page and the cheſs, to which they are wedged faſt by the quoins, to keep the form firm, in conjunction with the ſide-ſticks, which are placed at the ſide of the page, and fixed in the ſame manner by means of quoins.

STIFFLE, or GREAT MUSCLE, in the manege, is the part of the hind leg of a horſe which advances towards his belly. This is a moſt dangerous part to receive a blow upon.

STIGMA, a brand or impreſſion with a hot iron; a mark of infamy. See STIGMATIZING.

STIGMA, in *Botany*, the ſummit or top of the ſtyle, accounted by the ſexualiſts the female organ of generation in plants, which receives the fecundating duſt of the tops of the ſtamina, and tranſmits its vapour or effluvia through the ſtyle into the heart of the ſeed-bud, for the purpoſe of impregnating the ſeeds.

STIGMATA, in *Natural Hiſtory*, the apertures in different parts of the bodies of inſects communicating with the tracheæ or air-veſſels, and ſerving for the office of reſpiration.

STIGMATA, in antiquity, certain marks impreſſed on the left ſhoulders of the ſoldiers when liſted.

STIGMATA, were alſo a kind of notes or abbreviations, conſiſting only of points, diſpoſed various ways; as in triangles, ſquares, croſſes, &c.

STIGMATA, is alſo a term introduced by the Franciſcans, to expreſs the marks or prints of our Saviour's wounds, ſaid to have been miraculouſly impreſſed by him on the body of their ſeraphic father St Francis.

STIGMATIZING, among the ancients, was inflicted upon ſlaves as a puniſhment, but more frequently as a mark to know them by: in which caſe, it was done by applying a red-hot iron marked with certain letters to their foreheads, till a fair impreſſion was made; and then pouring ink into their furrows, that the inſcription might be the more conſpicuous.

Soldiers were branded in the hand with the name or character of their general.

After the ſame manner, it was cuſtomary to ſtigmatize the worſhippers and votaries of ſome of the gods. The marks uſed on theſe occaſions were various; ſometimes they contained the name of the god, ſometimes his particular enſign, as the thunderbolt of Jupiter, the trident of Neptune, the ivy of Bacchus, &c. or they marked themſelves with ſome myſtical number, whereby the god's name was deſcribed. To theſe three ways of ſtigmatizing St John is ſuppoſed to refer (Rev. chap. xiii. ver. 16, 17.). Theodoret is of opinion, that the

Jews were forbidden to brand themſelves with ſtigmata, becauſe the idolaters, by that ceremony, uſed to conſecrate themſelves to their falſe gods.

Among ſome nations, ſtigmatizing was conſidered as a diſtinguiſhing mark of honour and nobility. In Thrace, as Herodotus tells us *, it was practiſed by none but perſons of credit, nor omitted by any but perſons of the meaneſt rank. The ancient Britons are alſo ſaid to have imprinted on the bodies of their infants the figures of animals, and other marks, with hot irons.

* Lib. v.

STIL DE GRAIN, in the colour trade, the name of a compoſition uſed for painting in oil or water, and is made of a decoction of the lycium or Avignon berry, in alum-water, which is mixed with whiting into a paſte, and formed into twiſted ſticks. It ought to be choſen of a fine gold yellow, very fine, tender, and friable, and free from dirt.

STILAGO, a genus of plants belonging to claſs gynandria. See BOTANY *Index*.

STILBE, a genus of plants belonging to the claſs polygamia, and order of diœcia. See BOTANY *Index*.

STILBITE, a ſpecies of mineral, or variety of zeolite. See ZEOLITE, MINERALOGY *Index*.

STILE. See STYLE.

STILL, the name of an apparatus uſed in chemiſtry for various purpoſes, and in the diſtillation of ardent ſpirits.

STILL-Bottoms, in the diſtillery, a name given by the traders to what remains in the ſtill after working the waſh into low wines. Theſe bottoms are procured in the greateſt quantity from the malt-waſh, and are of ſo much value to the diſtiller in the fattening of hogs, &c. that he often finds them one of the moſt valuable articles of the buſineſs.

STILLINGFLEET, EDWARD, biſhop of Worceſter, was the ſon of Samuel Stillingfleet, gentleman, and was born at Cranborn in Dorſetſhire in 1635. He was educated at St John's College, Cambridge; and having received holy orders, was, in 1657, preſented to the rectory of Sutton in Nottinghamſhire. By publiſhing his *Origines Sacræ*, one of the ableſt defences of revealed religion that has ever been written, he ſoon acquired ſuch reputation, that was appointed preacher of the Rolls Chapel; and in January 1665 was preſented to the rectory of St Andrew's, Holborn. He was afterwards choſen lecturer at the Temple, and appointed chaplain in ordinary to King Charles II. In 1668 he took the degree of doctor of divinity; and was ſoon after engaged in a diſpute with thoſe of the Romiſh religion, by publiſhing his diſcourſe concerning the idolatry and fanaticiſm of the church of Rome, which he afterwards defended againſt ſeveral antagoniſts. In 1680 be preached at Guildhall chapel a ſermon on Phil. iii. 26. which he publiſhed under the title of *The Miſchief of Separation;* and this being immediately attacked by ſeveral writers, he in 1683 publiſhed his Unreaſonableneſs of Separation. In 1685 appeared his *Origines Britannicæ*, or the Antiquities of the Britiſh Church, in folio. During the reign of King James II. he wrote ſeveral tracts againſt popery, and was prolocutor of the convocation, as he had likewiſe been under Charles II. After the Revolution he was advanced to the biſhopric of Worceſter, and was engaged in a diſpute with the Socinians, and alſo with Mr Locke; in which laſt conteſt he is generally thought to have been unſucceſsful. He died at Weſtminſter in 1699, and was interred in the cathedral of Worceſter, where a monument was erected to his memory by his ſon. Dr Stillingfleet wrote other works beſides thoſe here mentioned, which, with the above, have been reprinted in 6 vols. folio.

STILLINGFLEET, *Benjamin*, an ingenious naturaliſt, was grandſon of the preceding. His father Edward was fellow of St John's College in Cambridge, F. R. S. M. D. and Greſham profeſſor of phyſic; but marrying in 1692, he loſt his lucrative offices and his father's favour; a misfortune that affected both himſelf and his poſterity. However, going into orders, he obtained, by his father's means, the living of Newington-Butts, which he immediately exchanged for thoſe of Wood-Norton and Swanton in Norfolk. He died in 1708.

Benjamin, his only ſon, was educated at Norwich ſchool, which he left in 1720, with the character of an excellent ſcholar. He then went to Trinity-College in Cambridge, at the requeſt of Dr Bentley, the maſter, who had been private tutor to his father, domeſtic chaplain to his grandfather, and much indebted to the family. Here he was a candidate for a fellowſhip, but was rejected by the maſter's influence. This was a ſevere and unexpected diſappointment, and but little alleviated afterwards by the Doctor's apology, that it was a pity that a gentleman of Mr Stillingfleet's parts ſhould be buried within the walls of a college.

Perhaps, however, this ingratitude of Dr Bentley was not of any real diſſervice to Mr Stillingfleet. By being thrown into the world, he formed many honourable and valuable connections. He dedicated ſome tranſlations of Linnæus to the late Lord Lyttleton, partly, he ſays, from motives of private reſpect and honour. Lord Barrington gave him, in a very polite manner, the place of the maſter of the barracks at Kenſington; a favour to which Mr Stillingfleet, in the dedication of his Calendar of Flora to that nobleman, alludes with equal politeneſs, as well as with the warmeſt gratitude. His Calendar of Flora was formed at Stratton in Norfolk in the year 1755, at the hoſpitable ſeat of his very worthy and ingenious friend Mr Marſham, who had made ſeveral obſervations of that kind, and had communicated to the public his curious obſervations on the growth of trees. But it was to Mr Wyndham of Felbrig in Norfolk that he appears to have had the greateſt obligations: he travelled abroad with him, ſpent much of his time at his houſe, and was appointed one of his executors (Mr Garrick was another), with a conſiderable addition to an annuity which that gentleman had ſettled upon him in his lifetime.

Mr Stillingfleet's genius ſeems, if we may judge from his works, to have led him principally to the ſtudy of natural hiſtory; which he proſecuted as an ingenious philoſopher, an uſeful citizen, and a good man. In this walk of learning he mentions, as his friends, Dr Watſon, Mr (afterwards Dr) Solander, Mr Hudſon, Mr Price of Foxley, and ſome others; to whom may be added the ingenious Mr Pennant. Nor can we omit the flattering mention which Mr Gray makes of him in one of his letters, dated from London in 1761: " I have lately made an acquaintance with this philoſopher, who lives in a garret here in the winter, that he may ſupport ſome near relations who depend upon him. He is always employed, conſequently (according to my old maxim)

maxim) always happy, always cheerful, and seems to me a very worthy honest man. His present scheme is to send some persons, properly qualified, to reside a year or two in Attica, to make themselves acquainted with the climate, productions, and natural history of the country, that we may understand Aristotle, Theophrastus, &c. who have been heathen Greek to us for so many ages; and this he has got proposed to Lord Bute, no unlikely person to put it in execution, as he is himself a botanist."

Mr Stillingfleet published a volume of miscellaneous tracts, which is in much esteem, and does great honour to his head and heart. They are chiefly translations of some essays in the *Amœnitates Academicæ*, published by Linnæus, interspersed with some observations and additions of his own. In this volume he shows also a taste for classical learning, and entertains us with some elegant poetical effusions of his own. But his Essay on Conversation, published in the first volume of Dodsley's Collection of Poems, entitles him to a distinguished rank among our English poets. This poem is addressed to Mr Wyndham, with all that warmth of friendship which distinguishes Mr Stillingfleet. As it is chiefly didactic, it does not admit of so many ornaments as some compositions of other kinds. However, it contains much good sense, shows a considerable knowledge of mankind, and has several passages that in point of harmony and easy versification would not disgrace the writings of our most admired poets. Here more than once Mr Stillingfleet shows himself still sore for Dr Bentley's cruel treatment of him; and towards the beautiful and moral close of it (where it is supposed he gives us a sketch of himself) seems to hint at a mortification of a more delicate nature, which he is said to have suffered from the other sex.

To these disappointments it was perhaps owing that Mr Stillingfleet neither married nor went into orders. His London residence was at a saddler's in Piccadilly; where he died in 1771, aged above 70, leaving several valuable papers behind him. He was buried in St James's church, without the slightest monument to his memory.

STILLINGIA, a genus of plants belonging to the class monœcia, and to the order of *monadelphia*. See BOTANY *Index*.

STILYARD. See *STEEL-Yard*.

STILPO, a celebrated philosopher of Megara, flourished under the reign of Ptolemy Euergetes. In his youth he had been addicted to licentious pleasures, from which he religiously refrained from the moment that he ranked himself among philosophers. When Ptolemy Soter, at the taking of Megara, offered him a large sum of money, and requested that he would accompany him into Egypt, he accepted but a small part of the offer, and retired to the island of Ægina, whence, on Ptolemy's departure, he returned to Megara. That city being again taken by Demetrius the son of Antigonus, and the philosopher required to give an account of any effects which he had lost during the hurry of the plunder, he replied, that he had lost nothing; for no one could take from him his learning and eloquence. So great was the fame of Stilpo, that the most eminent philosophers of Athens took pleasure in attending upon his discourses. His peculiar doctrines were, that species or universals have no real existence, and that one thing cannot be predicated of another. With respect to the former of these opinions, he seems to have taught the same doctrine with the sect afterwards known by the appellation of *Nominalists*. To prove that one thing cannot be predicated of another, he said, that *goodness* and *man*, for instance, are different things, which cannot be confounded by asserting the one to be the other: he argued farther, that goodness is an universal, and universals have no real existence; consequently since nothing cannot be predicated of any thing, goodness cannot be predicated of man. Thus, whilst this subtle logician was, through his whole argument, predicating one thing of another, he denied that any one thing could be the accident or predicate of another. If Stilpo was serious in this reasoning; if he meant any thing more than to expose the sophistry of the schools, he must be confessed to have been an eminent master of the art of wrangling; and it was not wholly without reason that Glycera, a celebrated courtezan, when she was reproved by him as a corrupter of youth, replied, that the charge might be justly retorted upon himself, who spent his time in filling their heads with sophistical quibbles and useless subtleties. In ethics he seems to have been a Stoic, and in religion he had a public and a private doctrine, the former for the multitude, and the latter for his friends. He admitted the existence of a supreme divinity, but had no reverence for the Grecian superstitions.

Enfield's History of Philosophy, vol. i.

STILOBATUM, in *Architecture*, denotes the body of the pedestal of any column.

STILTON, a town of England, in Huntingdonshire, 75 miles from London, south-west of Yaxley, on the Roman highway from Castor to Huntingdon, called *Ermine street*, some parts of which, in this neighbourhood, appear still paved with stone. This place is famous for cheese called *English Parmesan*, which is generally kept till it is old before it is brought to table, and even the process of decay is accelerated by various means, to render it agreeable to a vitiated taste. For making Stilton cheese, the following receipt is given in the first volume of the *Repository of Arts and Manufactures*:

"Take the night's cream, and put it to the morning's new milk, with the rennet; when the curd is come, it is not to be broken, as is done with other cheeses, but take it out with a soil-dish altogether, and place it in a sieve to drain gradually; and as it drains, keep gradually pressing it till it becomes firm and dry; then place it in a wooden hoop; afterwards to be kept dry on boards, turned frequently, with cloth binders round it, which are to be tightened as occasion requires, and changed every day until the cheese become firm enough to support itself; after the cloth is taken off, the cheese is rubbed every day all over, for two or three months, with a brush; and if the weather be damp or moist twice a-day; and even before the cloth is taken off, the top and bottom are well rubbed every day."

STIMULANTS, in *Medicine*, substances which increase the action of certain parts of the body. In particular, they quicken the motion of the blood, increase the action of the muscular fibres, and affect the nervous system.

STIMULI, in *Botany*, a species of armature or offensive weapon, with which some plants, as nettle, cassada, da, acalypha, and tragia, are furnished. Their use, says Linnæus, is by their venomous punctures to keep off naked animals that would approach to hurt them.

STING, an apparatus in the bodies of certain insects, in form of a little spear, serving them as a weapon of offence.

STING-Ray. See RAIA, ICHTHYOLOGY *Index*.

Falconer's Marine Dictionary. STINK-POT, an earthen jar or shell, charged with powder, grenadoes, and other materials of an offensive and suffocating smell. It is frequently used by privateers, in the western ocean, in the attack of an enemy whom he designs to board; for which purpose it is furnished with a light fuse at the opening or touch-hole. See BOARDING.

STINT, a species of bird. See TRINGA, ORNITHOLOGY *Index*.

STIPA, FEATHER GRASS, a genus of plants belonging to the class triandria, and order of digynia; and in the natural system ranging under the 4th order, *Gramina*. See BOTANY *Index*.

STIPEND, among the Romans, signifies the same with tribute; and hence *stipendarii* were the same with *tributarii*.

STIPEND, in *Scots Law*. See LAW, § clix. 12.

STIPULA, in *Botany*, one of the fulcra or props of plants, defined by Linnæus to be a scale, or small leaf, stationed on each side the base of the footstalks of the flower and leaves, at their first appearance, for the purpose of support. Elmgren restricts it to the footstalks of the leaves only.

STIPULATION, in the civil law, the act of stipulating, that is, of treating and concluding terms and conditions to be inserted in a contract. Stipulations were anciently performed at Rome, with abundance of ceremonies; the first whereof was, that one party should interrogate, and the other answer, to give his consent, and oblige himself. By the ancient Roman law, nobody could stipulate but for himself; but as the tabelliones were public servants, they were allowed to stipulate for their masters; and the notaries succeeding the tabelliones have inherited the same privilege.

STIRIA, a province of Germany, in the circle of Austria, with the title of a duchy. It is bounded on the north by the archduchy of Austria, on the east by Hungary, on the south by Carniola, and on the west by Carinthia and the archbishopric of Saltsburg; it is 125 miles in length and 17 in breadth, and is said to contain 22 cities, 95 towns, 338 castles, 15 convents, and 200,000 inhabitants. Though it is a mountainous country, yet there is a great deal of land fit for tillage, and the soil is so good, that the inhabitants never were in want of corn. It contains mines of very good iron; whence the arms made there are in great esteem. The women differ greatly from the Austrians, and are very plain and ingenious. They have all swellings on their throats, called *bronchoceles*. The men are also very simple, and are rather disposed to indulge in indolence. The chief town is Gratz.

STIRLING, a town of Scotland, situated on the river Forth, 35 miles north-west of Edinburgh, in W. Long. 3. 59. N. Lat. 56. 6. It is also called *Sterling* and *Striveling*; from the former of which Boethius falsely derives the name *Sterling money*; because, says he, Osbrit, a Saxon prince, after the overthrow of the Scots, established a mint there. The name of *Striveling* is said to have been derived from the frequency of strifes or conflicts in the neighbourhood. The town contains about 4000 inhabitants. It has a manufacture of tartans and shalloons, and employs about 30 looms in that of carpets. The great street is very broad. In it is the tolbooth, where is kept the standard for the wet measures of Scotland. The other streets are narrow and irregular.—Stirling is in miniature a resemblance of Edinburgh; being built on a rock of the same form, with a fortress on the summit. The origin of the castle is unknown. The rock of Stirling was strongly fortified by the Picts, amongst whom architecture and several other useful arts had made a considerable progress. As it lay in the extremities of their kingdom, the possession of it was the occasion of frequent contests betwixt them and their neighbours the Scots and Northumbrians; each of whose dominions did, for some time, terminate near it.

When the Scots, under Kenneth II. overthrew the Pictish empire near the middle of the ninth century, they endeavoured to obliterate every memorial of that people. They not only gave new names to provinces and towns, but, with all the rage of barbarians, demolished many magnificent and useful edifices which had been reared up by them, and this fortress among the rest. It was, however, soon rebuilt, though upon an occasion not very honourable to the Scots.

Upon the death of Kenneth II. in 855, his brother Donald V. mounted the throne of Scotland. In the beginning of his reign the kingdom was invaded by Osbrecht and Ella, two Northumbrian princes, who, uniting their forces with the Cumbrian Britons, and a number of Picts, who upon their expulsion from their native country had taken refuge in England, advanced to Jedburgh, where Donald encountered them; and, after a fierce and bloody battle, obtained a complete victory: but, having taken up his station in Berwick, in supine security, the Northumbrians, informed of the careless posture in which the Scottish army lay, surprised them by a hasty march, dispersed them, and made a prisoner of the king. Pursuing the advantage they had gained, they marched northward, and subdued all before them to the frith of Forth and the town of Stirling. But the forlorn situation of the Scots, without a king and without an army, obliging them to sue for peace, they obtained it, upon condition that they should pay a sum of money for the ransom of the king, and yield up all their dominions upon the south side of the Forth to the conquerors.

The Northumbrians taking possession of the territories ceded to them by this treaty, rebuilt the castle of Stirling, and planted it with a strong garrison, in order to preserve their new conquests, upon the frontiers of which it was situated. Our authorities also inform us, that they erected a stone bridge over the Forth, upon the summit of which a cross was raised, with the following inscription in monkish rhyme.

Anglos a Scotis separat crux ista remotis;
Armis hic stant Bruti, Scoti stant hic, cruce tuti.

Which is thus translated by Bellenden.

I am free marche, as passengeris may ken,
To Scottis, to Britonis, and to Inglismen.

None of the ancient English historians mentions this conquest. The whole story, as well as the inscription, wears

Stirling. wears much of a monkish garb; yet its authenticity is not a little confirmed by the arms of the town of Stirling, upon which is a bridge, with a cross, and the last line of the above Latin distich is the motto round it.

We must not, however, imagine, that in those times that fortress bore any resemblance to the present structure, which is adapted to the use of fire-arms. Its size and form probably resembled those castles which, under the feudal constitution, the English and Scottish barons used to erect upon their estates for dwelling-houses; and which, in those barbarous ages, they found necessary to fortify for their defence, not only against foreign invaders, but often against the attacks of their own neighbours. It is directly such a Gothic figure as this which represents the *Castrum Strivelense* upon the arms of Stirling.

This fortress, after it had continued in the possession of the Northumbrian Saxons about 20 years, was, together with the whole country upon the south side of the Forth, restored to the Scots, upon condition of their assisting the Saxons against their turbulent invaders the Danes. Upon the arms of Stirling are two branches of a tree, to represent the *Nemus Strivelense*; but the situation and boundaries of that forest, which was probably a wing of the Caledonian, cannot be ascertained. Upon the south of Stirling, vestiges of a forest are still discernible for several miles. Banks of natural timber still remain in the castle park, at Murray's wood, and near Nether Bannockburn; and stumps of trees, with much brushwood, are to be seen in all the adjacent fields.

When Kenneth III. received intelligence of the Danes having invaded his dominions, he appointed the castle of Stirling to be the place of rendezvous for his army; and he marched from thence to the battle of Loncarty, where he obtained a victory over those rovers, in the end of the 10th century.

In the 12th century, this castle is spoken of as a place of great importance, and one of the strongest fortresses in the kingdom. In 1174, a calamity, not unusual amongst the Scottish monarchs, befel William, who at that time occupied the throne. He was taken prisoner in an unsuccessful expedition which he made into England; and, after having been detained 12 months in captivity, was released, upon stipulating to pay a large sum of money for his ransom; and, until payment thereof, delivering into the hands of the English the four principal fortresses in the kingdom, which in those days were Stirling, Edinburgh, Roxburgh, and Berwick. This was the first great ascendant that England obtained over Scotland; and indeed the most important transaction which had passed between these kingdoms from the Norman conquest.

Though the Scottish monarchs, in their frequent perambulations through the kingdom, often visited Stirling, and held their courts for some time in the castle; yet it did not become a royal residence till the family of Stuart mounted the throne, and it was from different princes of this family that it received its present form. It was the place of the nativity of James II.; and, when raised to the throne, he frequently kept his court in it. It is well known to have been the place where that prince perpetrated an atrocious deed, the murder of William earl of Douglas, whom he stabbed with his own hand. The royal apartments were at that time in the north-west corner of the castle, and are now the residence of the fort-major. The room where the murder was committed still goes by the name of *Douglas's room*.

James III. contracting a fondness for the castle on account of its pleasant situation, made it the chief place of his residence, and added several embellishments to it. He built within it a magnificent hall, which in those days was deemed a noble structure, and is still entire. It now goes by the name of the *parliament-house*, having been designed for the accommodation of that supreme court. It was covered with an oaken roof of exquisite workmanship, which, though very little decayed, was a few years ago removed to make way for one of more modern structure. James also erected a college of secular priests in the castle, which he called the *chapel royal*, and which proved one cause of his own ruin. As the expences necessary for maintaining the numerous officers of such an institution were considerable, he annexed to it the revenues of the rich priory of Coldingham in the Merse, which at that time happened to become vacant. This priory had for a long time been holden by persons connected with the family of Hume; and that family, considering it as belonging to them, strongly opposed the annexation. The dispute seems to have lasted several years; for one parliament had passed a vote, annexing the priory to the chapel-royal, and a subsequent one enacted a statute prohibiting every attempt that was contrary or prejudicial to that annexation.

James V. was crowned in the castle of Stirling; and the palace, which is the chief ornament of it, was the work of that prince. This is a stately and commodious structure, all of hewn stone, with much statuary work upon it. It is built in form of a square, with a small court in the middle, in which the king's lions are said to have been kept; and hence it still goes by the name of the *lions den*. The palace contains many large and elegant apartments; the ground-story is now converted into barrack-rooms for the soldiers of the garrison; the upper affords a house for the governor, with lodgings for some of the subaltern officers.

Opposite to the palace, upon the north, stands an elegant chapel, which was built by James VI. for the baptism of his son, Prince Henry, in 1594. In this chapel is preserved the hulk of a large boat, which that whimsical monarch caused to be built and placed upon carriages, in order to convey into the castle the provisions for that solemnity.

A strong battery, with a tier of guns pointing to the bridge over the Forth, was erected during the regency of Mary of Lorraine, mother to Queen Mary. It is called the *French battery*, probably because constructed by engineers of that nation. The last addition was made to the fortifications in the reign of Queen Anne. Formerly they reached no farther than the old gate, upon which the flag-staff now stands: but in that reign they were considerably enlarged upon the side towards the town; and barracks, which are bomb-proof, with several other conveniences for a siege, were erected.

Upon the south side of the castle lies a park inclosed with a stone-wall, called the *king's park*, and near to the foot of the rock on which the castle stands, lay the royal gardens; vestiges of the walks and parterres, with a few stumps of fruit-trees, are still visible; but by long neglect, and the natural wetness of the soil, the place is now

now little better than a marsh. In the gardens is a mount of earth in form of a table, with benches of earth around it, where, according to tradition, the court sometimes held *fetes-champetres*. In the castle-hill is an hollow, comprehending about an acre of ground, and having all the appearance of an artificial work, which was used for jousts, tournaments, and other feats of chivalry.

Northward of the castle lies the Govan, or perhaps more properly the *Gowling* hill (A); in the middle of which is a small mount called *Hurly Haaky*, upon which Duke Mardoch and his two sons were executed for treasonable practices in the reign of James I.

The prospect from the castle is most delightful, as well as extensive, being greatly beautified, especially upon the east, by the windings of the Forth; which are so numerous, that though the distance by land from Stirling to Alloa is, in a straight line, not quite six miles, it is said to be 24 by water. As this river generally runs upon plain ground, it rolls its stream in so slow and silent a manner, that what Silius Italicus saith of the Ticinus is applicable to it, if, instead of *lucenti* in that poet, we should read *lutoso*; for the clay-banks, together with the tide, which flows above Stirling, render the Forth perpetually muddy:

> *Vix credas labi, ripis tam mitis opacis*
> *Somniferam ducit* lutolo *gurgite lympham.*

The lordship and castle of Stirling were a part of the usual dowry of the queens of Scotland, at least after the family of Stuart came to the throne, in which they were invested at their marriage.

Robert lord Erskine was appointed governor of the castle by King David II. and the office continued in that family till 1715.

This fortress hath been the scene of many transactions. Being by its situation considered as a key to the northern parts of the kingdom, the possession of it hath been always esteemed of great importance to those who sought to be masters of Scotland. It was undoubtedly a place of strength when the art of war by ordnance was in its infancy; but though it resisted the utmost efforts of the rebels in 1746, it could not now hold out three days if besieged by an army of a few thousand men conducted by an engineer of knowledge and integrity.

STIRLINGSHIRE, a county of Scotland, of which Stirling is the capital. It extends 20 miles in length and 12 in breadth; being bounded on the west by part of Lennox and Clydesdale; on the east, by Clackmannanshire, the river Forth, and part of Lothian; on the south-east, by Lothian; and on the north by Monteith. The face of the country is open and agreeable, diversified by hill and dale, well watered with streams and rivers; the principal of which is the Forth, rising in the neighbourhood of a high mountain called *Ben-Lomond*, and, running eastward, forms the frith of Edinburgh. The southern part is hilly, affording plenty of game, and pasturage for sheep, horses, and black cattle. The eastern part is fertile, producing plentiful harvests of corn, and great abundance of coal. Lead-ore is found in different parts of the county; and the rivers abound with pike, trout, and salmon.

The population of this county at two different periods, and according to the different parishes, will be seen in the following table:

	Parishes.	Population in 1755.	Population in 1790—1798.
	Airth	2316	2350
	Alva	436	612
	Baldernock	621	620
	Balfron	755	1381
5	Bothkennar	529	600
	Buchanan	1699	1111
	Campsie	1399	2517
	Denny	1392	1400
	Drymen	2789	1607

* Statist. Hist. of Scotland.

STIRRUP, in the manege, a rest or support for the horseman's foot, for enabling him to mount, and for keeping him firm in his seat.

Stirrups were unknown to the ancients. The want of them in getting upon horseback was supplied by agility or art. Some horses were taught to stoop to take their riders up; but the riders often leapt up by the help of their spears, or were assisted by their slaves, or made use of ladders for the purpose. Gracchus filled the highways with stones, which were intended to answer the same end. The same was also required of the surveyors of the roads in Greece as part of their duty.

Menage observes, that St Jerome is the first author who mentions them. But the passage alluded to is not to be found in his epistles; and if it were there, it would prove nothing, because St Jerome lived at a time when stirrups are supposed to have been invented, and after the use of saddles. Montfaucon denies the authenticity of this passage; and, in order to account for the ignorance of the ancients with regard to an instrument so useful and so easy of invention, he observes, that while cloths and housings only were laid upon the horses backs, on which the riders were to sit, stirrups could not have been used, because they could not have been fastened with the same security as upon a saddle. But it is more

Berenger's History and Art of Horsemanship, vol. i. p. 65.

(A) So called from the wailings and lamentations (in Scotch, *gowlings*) that were made for Duke Murdoch.

more probable, that in this inſtance, as in many others, the progreſs of human genius and invention is uncertain and ſlow, depending frequently upon accidental cauſes.

STIRRUP of a Ship, a piece of timber put upon a ſhip's keel, when ſome of her keel happens to be beaten off, and they cannot come conveniently to put or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ſhip's keel, and comes up on each ſide of the ſhip, where it is nailed ſtrongly with ſpikes; and this they call a ſtirrup.

STOBÆUS, JOHN, a laborious Greek writer, who lived at the end of the fourth century, compoſed many works, of which there are only his Collections remaining, and even theſe are not as he compoſed them; many things being inſerted by later authors. This work contains many important ſentiments collected from the ancient writers, poets, and philoſophers.

STOCK, in gardening, &c. the ſtem or trunk of a tree. What ſtock is moſt proper for each kind of fruit, ought as well to be conſidered and known, as what ſoil is moſt ſuitable to trees; for on theſe two things the future vigour of trees, and the goodneſs of fruit, equally depend. The beſt way for thoſe who intend to plant, is to raiſe their own ſtocks, by which they will be better aſſured of what they do; but if they ſhould buy their trees of nurſerymen, they ſhould diligently inquire upon what ſtocks they were propagated. See GRAFTING.

STOCK, in trade. See *CAPITAL Stock*.

STOCK-Broker. See BROKER and STOCKS.

STOCK-Dove. See COLUMBA, ORNITHOLOGY *Index*.

STOCK-Jobbing, the art or myſtery of trafficking in the public ſtocks or funds. See FUND and *Stock-JOBBING*.

STOCK Gilly-flower. See CHEIRANTHUS, BOTANY *Index*.

STOCKHOLM, the capital of Sweden, is ſituated in the province of Upland, in E. Long. 19. 30. and N. Lat. 59. 20. Its foundation is by the beſt Swediſh writers generally attributed to Birger Jarl, regent of the kingdom about the middle of the 13th century during the minority of his ſon Waldemar, who had been raiſed to the throne by the ſtates of the kingdom; but it was not before the 18th century that the royal reſidence was transferred from Upſala to this city.

This capital, which is very long and irregular, occupies, beſide two peninſulas, ſeven ſmall rocky iſlands, ſcattered in the Mæler, in the ſtreams which iſſue from that lake, and in a bay of the gulf of Bothnia. A variety of contraſted and enchanting views are formed by numberleſs rocks of granite riſing boldly from the ſurface of the water, partly bare and craggy, partly dotted with houſes, or feathered with wood. The harbour is an inlet of the Baltic: the water is clear as cryſtal, and of ſuch depth that ſhips of the largeſt burthen can approach the quay, which is of conſiderable breadth, and lined with ſpacious buildings and ware houſes. At the extremity of the harbour ſeveral ſtreets riſe one above another in the form of an amphitheatre; and the palace, a magnificent building, crowns the ſummit. Towards the ſea, about two or three miles from the town, the harbour is contracted into a narrow ſtrait, and, winding among high rocks, diſappears from the ſight; and the proſpect is terminated by diſtant hills, overſpread with foreſt. It is far beyond the power of words, or of the pencil, to delineate theſe ſingular views. The central iſland, from which the city derives its name, and the Ritterholm, are the handſomeſt parts of the town. Excepting in the ſuburbs, where the houſes are of wood painted red, the generality of the buildings are of ſtone, or brick ſtuccoed white. The royal palace, which ſtands in the centre of Stockholm, and upon the higheſt ſpot of ground, was begun by Charles XI.: it is a large quadrangular ſtone edifice, and the ſtyle of architecture is both elegant and magnificent.

Coxe's Travels, vol. ii.

It is the habitation not only of the royal family, but alſo of the greater part of the officers belonging to the houſehold. It likewiſe comprehends the national or ſupreme court of juſtice, the colleges of war, chancery, treaſury, and commerce; a chapel, armoury, library, and office for the public records; but the greater number of inferior officers and ſervants belonging to the court, are, with the foot-guards, quartered on the burghers. The caſtle, and all the ſtately edifices in the kingdom, are covered with copper. The palace of the nobility, in which this order ſits during the ſeſſion of the diet, is an elegant building adorned on the outſide with marble ſtatues and columns, and on the inſide with painting and ſculpture. This and three other palaces ſtand on the banks of the lake, and are built on the ſame model, ſo as to compoſe an uniform piece of architecture. The bank, built at the expence of the city, is a noble edifice, and joins with many ſumptuous houſes belonging to the nobility in exhibiting a ſplendid appearance. The houſes of the burghers are generally built of brick in the city; but in the ſuburbs they are commonly made up of timber, and therefore very ſubject to conflagrations. Theſe houſes are often framed in Finland, according to the plan and dimenſions preſcribed: whence they are tranſported in pieces to Stockholm by water, and there ſet up by the carpenters. Theſe wooden habitations, if kept in proper repair, will laſt 30 or 40 years, and are deemed warmer, neater, and more healthy, than thoſe of brick or ſtone. To prevent the danger of conflagrations, the city is divided into 12 wards. In each of theſe there is a maſter and four aſſiſtants, who forthwith repair to the place where the fire breaks out; and all porters and labourers are obliged to range themſelves under the maſter of the ward to which they belong. A fire-watch patroles the ſtreets by night, to give warning or aſſiſtance as it may be wanted; and a centinel is maintained in the ſteeple of every church, to toll the bell on the firſt appearance of any ſuch accident. The police of Stockholm is entirely ſubjected to the regulations of the grand governor, aſſiſted by a deputy and bailiff of the caſtle. This city is the emporium of Sweden, to which all the commodities of the kingdom are brought for exportation, and where almoſt all the imports from abroad are depoſited. The port or haven formed by the lake Mæler is large enough to contain 1000 ſail of ſhipping; and furniſhed with a key or wharf about an Engliſh mile in length, to which the veſſels may lie with their broadſides. The greateſt inconveniences attending this ſituation are, the diſtance from the ſea, which is not within leſs than 10 miles of the town; the want of tides; and the winding of the river, which is remarkably crooked. It opens into the Baltic; and the entrance, which is dangerous and rocky, the Swedes have ſecured with two ſmall forts: within, it is perfectly ſafe and commodious.

dious. The northern ſuburbs are remarkable for the king's gardens, and for the great number of artiſans who have choſen their habitations in this quarter. In the ſouthern ſuburbs the Muſcovite commodities are ſold; and here is a magnificent exchange where the merchants daily aſſemble. Population 80,000.

STOCKING, that part of the clothing of the leg and foot which immediately covers and ſcreens them from the rigour of the cold. Anciently, the only ſtockings in uſe were made of cloth, or of milled ſtuffs ſewed together; but ſince the invention of knitting and weaving ſtockings of ſilk, wool, cotton, thread, &c. the uſe of cloth ſtockings is quite diſcontinued. Dr Howel, in his Hiſtory of the World (vol. ii. p. 222.) relates, that Queen Elizabeth, in 1501, was preſented with a pair of black knit ſilk ſtockings by her ſilk-woman, and thenceforth ſhe never wore cloth ones any more. The ſame author adds, that King Henry VIII. ordinarily wore cloth hoſe, except there came from Spain, by great chance, a pair of ſilk ſtockings. His ſon, King Edward VI. was preſented with a pair of long Spaniſh ſilk ſtockings by Sir Thomas Greſham, and the preſent was then much taken notice of. Hence it ſhould ſeem, that the invention of ſilk knit ſtockings originally came from Spain. Others relate, that one William Rider, an apprentice on London bridge, ſeeing at the houſe of an Italian merchant a pair of knit worſted ſtockings from Mantua, took the hint, and made a pair exactly like them, which he preſented to William earl of Pembroke, and that they were the firſt of that kind worn in England, anno 1564.

The modern ſtockings, whether woven or knit, are formed of an infinite number of little knots, called *ſtitches*, *lo ps*, or *meſhes*, intermingled in one another.

Knit ſtockings are wrought with needles made of poliſhed iron or braſs wire, which interweave the threads and form the meſhes the ſtocking conſiſts of. At what time the art of knitting was invented it is perhaps impoſſible to determine, though it has uſually been attributed to the Scots, as it is ſaid that the firſt works of this kind came from Scotland. It is added, that it was on this account that the company of ſtocking-knitters, eſtabliſhed at Paris 1527, took for their patron St Fiacre, who is ſaid to have been the ſon of a king of Scotland. But it is moſt probable that the method of knitting ſtockings by wires or needles was firſt brought from Spain.

Woven ſtockings are generally very fine; they are manufactured on a frame or machine made of poliſhed iron, the ſtructure of which it is needleſs to deſcribe, as it may be ſeen in almoſt every conſiderable town in Great Britain. The invention of this machine is, by Mr Anderſon, attributed to Williaw Lee, M. A. of St John's College, Cambridge, at a period ſo early as 1589. Others have given the credit of this invention to a ſtudent of Oxford at a much later period, who, it is ſaid by Aaron Hill *, was driven to it by dire neceſſity. This young man, falling in love with an innkeeper's daughter, married her though ſhe had not a penny, and he by his marriage loſt a fellowſhip. They ſoon fell into extreme poverty; and their marriage producing the conſequences naturally to be expected from it, the amorous pair became miſerable, not ſo much on account of their ſufferings, as from the melancholy dread of what would become of their yet unborn infant. Their only means of ſupport were the knitting of ſtockings, at which the woman was very expert: "But ſitting conſtantly together from morning to night, and the ſcholar often fixing his eyes, with ſtedfaſt obſervation, on the motion of his wife's fingers in the dexterous management of her needles, he took it into his imagination, that it was not impoſſible to contrive a little loom which might do the work with much more expedition. This thought he communicated to his wife, and joining his head to her hands, the endeavour ſucceeded to their wiſh. Thus the ingenious ſtocking-loom, which is ſo common now, was firſt invented; by which he did not only make himſelf and his family happy, but has left his nation indebted to him for a benefit which enables us to export ſilk ſtockings in great quantities, and to a vaſt advantage, to thoſe very countries from whence before we uſed to bring them at conſiderable loſs in the balance of our traffic."

* See *An Account of the Riſe and Progreſs of the Beech Oil Invention*, &c. 8vo. 1715.

STOCKS, *or* Public Funds *in England.* By the word *ſtock* was originally meant a particular ſum of money contributed to the eſtabliſhing a fund to enable a company to carry on a certain trade, by means of which the perſon became a partner in that trade, and received a ſhare of the profit made thereby, in proportion to the money employed. But this term has been extended farther, though improperly, to ſignify any ſum of money which has been lent to the government, on condition of receiving a certain intereſt till the money is repaid, and which makes a part of the national debt. As the ſecurity both of the government and of the public companies is eſteemed preferable to that of any private perſon, as the ſtocks are negociable and may be ſold at any time, and as the intereſt is always punctually paid when due; ſo they are thereby enabled to borrow money on a lower intereſt than what could be obtained from lending it to private perſons, where there muſt be always ſome danger of loſing both principal and intereſt.

But as every capital ſtock or fund of a company is raiſed for a particular purpoſe, and limited by parliament to a certain ſum, it neceſſarily follows, that when that fund is completed, no ſtock can be bought of the company; though ſhares already purchaſed may be transferred from one perſon to another. This being the caſe, there is frequently a great diſproportion between the original value of the ſhares and what is given for them when transferred: for if there are more buyers than ſellers, a perſon who is indifferent about ſelling will not part with his ſhare without a conſiderable profit to himſelf; and on the contrary, if many are diſpoſed to ſell, and few inclined to buy, the value of ſuch ſhares will naturally fall in proportion to the impatience of thoſe who want to turn their ſtock into ſpecie.

A ſtock may likewiſe be affected by the court of chancery: for if that court ſhould order the money, which is under their direction, to be laid out in any particular ſtock, that ſtock, by having more purchaſers, will be raiſed to a higher price than any other of the like value.

By what has been ſaid, the reader will perceive how much the credit and intereſt of the nation depends on the ſupport of the public funds. While the annuities and intereſt for money advanced is there regularly paid, and the principal inſured by both prince and people (a security not to be had in other nations, foreigners will lend us their property, and all Europe be interested in our welfare; the paper of the companies will be converted into money and merchandise, and Great Britain can never want cash to carry her schemes into execution. See the article FUND.

STOCKS, a frame erected on the shore of a river or harbour, whereon to build shipping. It generally consists of a number of wooden blocks, ranged parallel to each other, at convenient distances, and with a gradual declivity towards the water.

STOCKS, a wooden machine to put the legs of offenders in, for securing disorderly persons, and by way of punishment in divers cases, ordained by statute, &c.

STOCKTON upon Tees, a handsome town in the county of Durham, about 16 miles south of the city of Durham. It is now a port of considerable trade; though, at the restoration, it was a despicable village, the best house in which could hardly boast of any thing better than clay-walls and a thatched roof. About 40 years ago it sent out in one year 75 vessels for the port of London; and the trade is much increased since.

STOEBE, BASTARD ÆTHIOPIAN, a genus of plants belonging to the class syngenesia; and in the natural system ranging under the 49th order *compositæ*. See BOTANY *Index*.

STOKESIA, a genus of plants belonging to the syngenesia class, and order of polygamia æqualis. The corollets in the ray are disposed in the shape of a funnel, and are long and irregular. The down is four-bristled, and the receptacle is naked. One species only is known, which is a herbaceous plant, and a native of South Carolina.

STOICS, the name given to a sect of Grecian philosophers, from Στοα, "the porch in Athens," which the founder of the sect chose for his school. For the peculiar tenets of this sect, see METAPHYSICS, Chap. iv. Part 3. MORAL PHILOSOPHY, n° 8. and ZENO.

STOLBERG, a small town of Germany, in the circle of Upper Saxony, and territory of Thuringia, of which it is the capital place. It is situated between two mountains, 50 miles north-west of Leipsic. E. Long. 11. 8. N. Lat. 51. 42.

STOLE, a sacerdotal ornament worn by the Romish parish priests above their surplice, as a mark of superiority in their respective churches; and by other priests over the alb, at celebrating of mass, in which case it goes across the stomach; and by deacons, over the left shoulder, scarf-wise: when the priest reads the gospel for any one, he lays the bottom of his stole on his head. The stole is a broad swath, or slip of stuff, hanging from the neck to the feet, with three crosses thereon.

Groom of the STOLE, the eldest gentleman of his Majesty's bedchamber, whose office it is to present and put on his Majesty's first garment, or shirt, every morning, and to order the things in the chamber.

STOMACH, in *Anatomy*. See ANATOMY, n° 91.

STOMACHIC MEDICINES are such as strengthen the stomach and promote digestion, &c.

Stomachic corroboratives are such as strengthen the tone of the stomach and intestines; among which are carminatives, as the roots of galangals, red gentian, zedoary, pimpinella, calamus aromaticus, and arum. Of barks and rinds, those of canella alba, sassafras, citrons, Seville and China oranges, &c. Of spices, pepper, ginger, cloves, cinnamon, cardamums, and mace.

STOMOXYS, a genus of insects belonging to the order of diptera. See ENTOMOLOGY, p. 214.

STONE, EDMUND, a distinguished self-taught mathematician, was born in Scotland; but neither the place nor the time of his birth is well known; nor have we any memoirs of his life, except a letter from the Chevalier de Ramsay, author of the Travels of Cyrus, in a letter to Father Castel, a Jesuit at Paris, and published in the Memoirs de Trevoux, p. 109, as follows: "True genius overcomes all the disadvantages of birth, fortune, and education; of which Mr Stone is a rare example. Born a son of a gardener of the duke of Argyle, he arrived at eight years of age before he learnt to read.—By chance a servant having taught young Stone the letters of the alphabet, there needed nothing more to discover and expand his genius. He applied himself to study, and he arrived at the knowledge of the most sublime geometry and analysis, without a master, without a conductor, without any other guide but pure genius.

"At 18 years of age he had made these considerable advances without being known, and without knowing himself the prodigies of his acquisitions. The duke of Argyle, who joined to his military talents a general knowledge of every science that adorns the mind of a man of his rank, walking one day in his garden, saw lying on the grass a Latin copy of Sir Isaac Newton's celebrated *Principia*. He called some one to him to take and carry it back to his library. Our young gardener told him that the book belonged to him. 'To you?' replied the duke. 'Do you understand geometry, Latin, Newton?' I know a little of them, replied the young man with an air of simplicity arising from a profound ignorance of his own knowledge and talents. The duke was surprised; and having a taste for the sciences, he entered into a conversation with the young mathematician: he asked him several questions, and was astonished at the force, the accuracy, and the candour of his answers. 'But how (said the duke) came you by the knowledge of all these things?' Stone replied, 'A servant taught me, ten years since, to read: Does one need to know any thing more than the 24 letters in order to learn every thing else that one wishes?' The duke's curiosity redoubled—he sat down upon a bank, and requested a detail of all his proceedings in becoming so learned.

"I first learned to read, said Stone: the masons were then at work upon your house: I went near them one day, and I saw that the architect used a rule, compasses, and that he made calculations. I inquired what might be the meaning and use of these things; and I was informed that there was a science called Arithmetic: I purchased a book of arithmetic, and I learned it.—I was told there was another science called Geometry: I bought the books, and I learnt geometry. By reading I found that there were good books in these two sciences in Latin: I bought a dictionary, and I learned Latin. I understood also that there were good books of the same kind in French: I bought a dictionary, and I learned French. And this, my lord, is what I have done: it seems to me that we may learn every thing when we know the 24 letters of the alphabet."

"This account charmed the Duke. He drew this wonderful

wonderful genius out of his obfcurity; and he provided him with an employment which left him plenty of time to apply himfelf to the fciences. He difcovered in him alfo the fame genius for mufic, for painting, for architecture, for all the fciences which depend on calculations and proportions."

"I have feen Mr Stone. He is a man of great fimplicity. He is at prefent fenfible of his own knowledge; but he is not puffed up with it. He is poffeffed with a pure and difinterefted love for the mathematics, though he is not folicitous to pafs for a mathematician; vanity having no part in the great labour he fuftains to excell in that fcience. He defpifes fortune alfo; and he has folicited me twenty times to requeft the duke to give him lefs employment, which may not be worth the half of that he now has, in order to be more retired, and lefs taken off from his favourite ftudies. He difcovers fometimes, by methods of his own, truths which others have difcovered before him. He is charmed to find on thefe occafions that he is not a firft inventor, and that others have made a greater progrefs than he thought. Far from being a plagiary, he attributes ingenious folutions, which he gives to certain problems, to the hints he has found in others, although the connection is but very diftant," &c.

Mr Stone was author and tranflator of feveral ufeful works; viz. 1. A New Mathematical Dictionary, in 1 vol. 8vo, firft printed in 1726. 2. Fluxions, in 1 vol. 8vo, 1730. The Direct Method is a tranflation from the French, of Hofpital's Analyfe des Infiniments Petits; and the Inverfe Method was fupplied by Stone himfelf. 3. The Elements of Euclid, in 2 vols. 8vo, 1731. A neat and ufeful edition of thofe Elements, with an account of the life and writings of Euclid, and a defence of his Elements againft modern objectors. Befide other fmaller works. Stone was a fellow of the Royal Society, and had inferted in the Philofophical Tranfactions (vol. xli. p. 218), an "Account of two fpecies of lines of the 3d order, not mentioned by Sir Ifaac Newton or Mr Stirling."

STONE, *Jerome*, the fon of a reputable feaman, was born in the parifh of Scoonie, in the county of Fife, North Britain. His father died abroad when he was but three years of age, and his mother, with her young family, was left in very narrow circumftances. Jerome, like the reft of the children, having got the ordinary fchool education, reading Englifh, writing, and arithmetic, betook himfelf to the bufinefs of a travelling chapman. But the dealing in buckles, garters, and fuch fmall articles, not fuiting his fuperior genius, he foon converted his little ftock into books, and for fome years went through the country, and attended the fairs as an itinerant bookfeller. There is great reafon to believe that he engaged in this new fpecies of traffic, more with a view to the improvement of his mind than for any pecuniary emolument. Formed by nature for literature, he poffeffed a peculiar talent for acquiring languages with amazing facility. Whether from a defire to underftand the Scriptures in their original languages, or from being informed that thefe languages are the parents of many others, he began his philological purfuits with the ftudy of the Hebrew and Greek tongues; and, by a wonderful effort of genius and application, made himfelf fo far mafter of thefe, without any kind of affiftance, as to be able to interpret the Hebrew Bible and Greek Teftament into Englifh *ad aperturam libri*. At this time he did not know one word of Latin. Senfible that he could make no great progrefs in learning, without the knowledge of at leaft the grammar of that language, he made application to the parifh fchoolmafter for his affiftance. Some time afterwards, he was encouraged to profecute his ftudies at the univerfity of St Andrews. An unexampled proficiency in every branch of literature recommended him to the efteem of the profeffors; and an uncommon fund of wit and pleafantry rendered him, at the fame time, the favourite of all his fellow ftudents, fome of whom fpeak of him to this day with an enthufiaftic degree of admiration and refpect. About this period fome very humorous poetical pieces of his compofition were publifhed in the Scots Magazine. Before he had finifhed his third feffion, or term, at St Andrew's, on an application to the college by the mafter of the fchool of Dunkeld for an ufher, Mr Stone was recommended as the beft qualified for that office; and about two or three years after, the mafter being removed to Perth, Mr Stone, by the favour of his Grace the Duke of Atholl, who had conceived a high opinion of his abilities, was appointed his fucceffor.

When he firft went to Dunkeld, he entertained but an unfavourable opinion of the Gaelic language, which he confidered as nothing better than a barbarous inarticulate gibberifh; but being bent on inveftigating the origin and defcent of the ancient Scots, he fuffered not his prejudices to make him neglect the ftudy of their primitive tongue. Having, with his ufual affiduity and fuccefs, maftered the grammatical difficulties which he encountered, he fet himfelf to difcover fomething of the true genius and character of the language. He collected a number of ancient poems, the production of Irifh or Scottifh bards, which, he faid, were daring, innocent, paffionate, and bold. Some of thefe poems were tranflated into Englifh verfe, which feveral perfons now alive have feen in manufcript, before Mr Macpherfon publifhed any of his tranflations from Offian.

He died while he was writing and preparing for the prefs a treatife, intitled, "An Inquiry into the Original of the Nation and Language of the ancient Scots, with Conjectures about the Primitive State of the Celtic and other European Nations;" an idea which could not have been conceived by an ordinary genius. In this treatife he proves that the Scots drew their original, as well as their language, from the ancient Gauls. Had Mr Stone lived to finifh this work, which difcovers great ingenuity, immenfe reading, and indefatigable induftry, it would have thrown light upon the dark and early periods of the Scottifh hiftory, as he opens a new and plain path for leading us through the unexplored labyrinths of antiquity. But a fever put an end to his life, his labours, and his ufefulnefs, in the year 1757, being then only in the 30th year of his age. He left, in manufcript, a much efteemed and well-known allegory, intitled "The Immortality of Authors," which has been publifhed and often reprinted fince his death, and will be a lafting monument of a lively fancy, found judgement, and correct tafte. It was no fmall ornament of this extraordinary character, that he paid a pious regard to his aged mother, who furvived him two years, and received an annual penfion from the Duchefs of Atholl as a teftimony of refpect to the memory of her fon.

STONEHIVE,

STONEHIVE, or STONEHAVEN, a ſmall town in the county of Kincardine, in Scotland, 15 miles ſouth from Aberdeen. It was built in the time of Charles II. and ſtands at the foot of ſome high cliffs, in a ſmall bay, with a rocky bottom, opening a little in one part, ſo that ſmall veſſels may find admittance, but only at high water. A pier runs out from the harbour on the north ſide to ſecure them after their entrance. The town contains about 800 inhabitants. The manufactures are ſail-cloths and oſnaburghs, knit worſted and thread ſtockings.

STONES, in *Natural Hiſtory*, have been defined bodies which are inſipid, not ductile, nor inflammable, nor ſoluble in water. For a view of the claſſification of ſtones and of their diſtribution, ſee MINERALOGY and GEOLOGY.

Here we ſhall make a few obſervations on ſome ſpeculative diſcuſſions relative to their natural hiſtory.

As philoſophers have perplexed themſelves much about the origin and formation of the earth (a ſubject certainly far beyond the ken of the human intellect, at leaſt if we believe that it was made by the Almighty power of God), ſo they have alſo propoſed theories to explain the origin of ſtones. When philoſophers limit their inquiries within the boundaries of ſcience, where they are led by the ſober and ſafe conduct of obſervation and experiment, their concluſions may be ſolid and may be uſeful; but when, throwing experiment and obſervation aſide, they rear a theory upon an airy nothing, or upon a ſingle detached fact, their theories will vaniſh before the touch of true philoſophy as a romantic palace before the rod of the enchanter. Sometimes from whim, or caprice, or vanity, they attempt to confound every thing: they wiſh to prove that the ſoul is mere matter, that plants are animals, and that foſſils are plants, and thus would baniſh two ſubſtances, ſpirit and dead matter, entirely from the world; as if the Author of Nature were actuated by ſordid views of parſimony in the works of creation, though we evidently ſee that a generous profuſion is one of the characteriſtic marks of theſe works. We leave the taſk of confounding the different claſſes of being to thoſe philoſophers whoſe minds are too contracted to comprehend a great variety of being at one view, or who prefer novelty to every thing elſe. We content ourſelves with the old opinion, that the ſoul is a ſpiritual ſubſtance; that plants are plants, and that ſtones are ſtones.

We have been led into theſe remarks by finding that ſome philoſophers ſay that ſtones are vegetables; that they grow and increaſe in ſize like a plant. This theory, we believe, was firſt offered to the world by M. Tournefort, in the year 1702, after returning from his travels in the eaſt. It was founded on a curious fact. In ſurveying the labyrinth of Crete, he obſerved that the names which viſitors had engraved upon the rock were not formed of hollow but of prominent letters like baſſo relievos. He ſuppoſes that theſe letters were at firſt hollowed out by knives; that the hollows have ſince been filled up by the growth of the ſtone; and hence he concludes that ſtones vegetate. We wiſh we were fully aſſured of the fact that the letters were at firſt hollowed, before we attempt to account for their prominency. But even allowing the ſuppoſition to be true that they were at firſt hollow, we reply it is only a ſingle fact, and that it is altogether unphiloſophical to deduce a general ſyſtem from a ſingle fact.

In the *ſecond* place, this protuberancy of the characters is very improperly called vegetation, for it is not produced by a proceſs in any reſpect like the vegetation of a plant. Vegetation ſuppoſes veſſels containing fluids and growth by expanſion; but who ever heard of veſſels in a ſtone, of fluids moving in them, or of the different parts expanding and ſwelling like the branch or trunk of a tree? Even the fact which Tournefort mentions proves nothing. He does not pretend to ſay, that the rock itſelf is increaſing, but only that a few ſmall hollows are filled with new ſtony matter, which riſes a little above the ſurrounding ſurface of the rock. This matter evidently has been once liquid, and at length has congealed in the channel into which it had run. But is not this eaſily explained by a common proceſs, the formation of ſtalactites? When water charged with calcareous matter is expoſed to the action of air, the water evaporates, and leaves the calcareous earth behind, which hardens and becomes like a ſtone.

Having thus examined the principal fact upon which M. Tournefort founds his theory, it is unneceſſary to follow him minutely through the reſt of his ſubject.—He compares the accretion of matter in the labyrinth to the conſolidation of a bone when broken, by a callus formed of the extravaſated nutritious juice. This obſervation is thought to be confirmed, by finding that the projecting matter of the letters is whitiſh and the rock itſelf greyiſh. But it is eaſy to find compariſons. The difficulty, as Pope ſays, is to apply them. The reſemblance between the filling up of the hollow of a ſtone, and the conſolidation of a broken bone by a callus, we confeſs ourſelves not philoſophers enough to ſee. Were we writing poetry in bad taſte, perhaps it might appear. The circumſtance, that the prominent matter of the letters is whitiſh, while the rock is greyiſh, we flatter ourſelves ſtrengthens our ſuppoſition that it conſiſts of a depoſition of calcareous matter. Upon the whole, we conclude, we hope logically, that no ſuch theory as this, that ſtones are vegetables, can be drawn from the ſuppoſed fact reſpecting the labyrinth. We have to regret, that the account which we have ſeen of the ſubject is ſo imperfect, that we have not ſufficient materials for a proper inveſtigation. Tournefort has not even told us of what kind of ſtone or earth the accretion conſiſts; yet this ſingle information would probably have decided the queſtion (A).

(A) To give a more diſtinct notion of Tournefort's theory, we ſhall ſubjoin his concluſions: From theſe obſervations (he ſays) it follows, that there are ſtones which grow in the quarries, and of conſequence that are fed; that the ſame juice which nouriſhes them ſerves to rejoin their parts when broken; juſt as in the bones of animals, and the branches of trees, when kept up by bandages; and, in a word, that they vegetate. There is, then (he ſays), no room to doubt but that they are organized; or that they draw their nutritious juice from the

STONES AND EARTHS, Analysis of.

Preliminary Processes.

AT the close of our article Mineralogy, we referred to this place for an account of the method of examining the chemical conſtitution of earths and ſtones. In the article Ores, we have given a pretty full detail of the methods of analyſing that claſs of minerals. In this place we propoſe briefly to point out the moſt improved proceſſes for the analyſis of the other three claſſes of mineral bodies, viz. earths and ſtones, ſalts, and combuſtibles; to which we ſhall add ſome account of the method of examining ſoils.

But before proceeding to the immediate object of this treatiſe, it may be uſeful to make ſome obſervations on ſome preliminary proceſſes connected with the ſubject under conſideration.

In the firſt place, it is neceſſary that the mineral to be examined be reduced to a fine powder. To effect this with very hard ſtones, they are made red hot, and in this ſtate thrown into cold water. By the ſudden change of temperature in the different parts of the ſtone, it cracks, and falls to pieces. If the pieces be not ſufficiently ſmall, the ſame proceſs is to be repeated. The fragments are then to be reduced to ſmaller pieces in a poliſhed ſteel mortar, and the cavity of this mortar ought to be cylindrical. A peſtle of the ſame metal ſhould be made to fit it exactly, that no part of the ſtone may eſcape during the operation of pounding. The ſtone being in this way reduced to powder, a determinate quantity is taken, 100 or 200 grains, for example, and this is to be reduced to as fine a powder as poſſible; or, as it is called, to an impalpable powder. This operation is moſt ſucceſsfully performed in an agate mortar, with a peſtle of the ſame mineral; a mortar of about four inches in diameter, and rather more than one inch deep, is found to anſwer the purpoſe very well. It is found moſt convenient to operate on ſmall quantities only at a time; not more than five or ſix grains. When the powder feels ſoft, adheres, and appears under the peſtle in the form of a cake, it is then as fine as poſſible. It is now to be accurately weighed, and it is uſually found to have acquired ſome additional weight, ariſing from part of the mortar being worn off during the pounding. This additional weight muſt be attended to, and after the analyſis is completed, a part of the ſubſtance of the mortar muſt be ſubtracted. In the caſe of an agate or flint mortar being uſed, the portion rubbed off, which increaſes the weight, may be regarded as pure ſiliceous earth.

The chemical veſſels neceſſary for the analyſis of minerals are crucibles for expoſing the ſubſtances to heat, glaſſes and ſhallow diſhes for ſolutions and evaporations. The crucibles ſhould be of platina or pure ſilver, and of ſuch a capacity as to hold from ſeven to eight cubic inches of water. The veſſels in which the ſolutions, evaporations, and other proceſſes are performed, ſhould be of glaſs or porcelain; the glaſs veſſels, as being more brittle, and therefore more apt to break, are found to be leſs economical than thoſe of porcelain. Some chemiſts employ porcelain veſſels which are in the form of ſections of ſpheres, and are glazed both in the inſide and outſide, excepting part of the bottom, which comes into immediate contact with the fire. Wedgewood's glazed veſſels for evaporations, are found to anſwer very well; the glaze is thin, and the veſſels are not very apt to crack; but it is ſuppoſed by ſome chemiſts, that it is occaſionally acted on by ſtrong acids. It is ſcarcely neceſſary to add, that an accurate balance is a neceſſary inſtrument in the hands of the analyſt.

I. *Of the Analyſis of Earths and Stones.*

The ingredients which have been diſcovered by means of analyſis, in the compoſition of ſimple ſtones are, ſilica, alumina, lime, magneſia, zirconia, and glucina, with ſome of the metallic oxides, as thoſe of iron, copper, mangeneſe, chromium, and nickel; but it never happens that the whole of theſe ſubſtances are found in combination; and indeed it is a rare circumſtance to meet with more than four or five in the ſame ſtone. With a view of diſcovering the different ſubſtances which enter into the compoſition of ſtones, the following method is recommended.

Take 200 grains of the ſtone to be examined, or, if it be inconvenient to procure this quantity, 100 grains will be ſufficient. Let it be reduced to a fine powder, mixed with three times its weight of pure potaſh, and a ſmall portion of water, and then ſubjected to heat in a crucible of ſilver. The heat muſt be applied ſlowly at firſt, and the matter is to be conſtantly ſtirred, that no part of it may be thrown out of the crucible by the ſwelling of the potaſh. The water being evaporated, the mixture is to be kept at a red heat for half an hour; and being removed from the furnace, ſome notion may be formed of the nature of the ingredients, by examining the contents; for, if the mixture be in a liquid ſtate, the ſtone is chiefly compoſed of ſiliceous earth; if it be of the conſiſtence of paſte, and have an opaque appearance,

---

the earth. This juice muſt be firſt filtrated and prepared in their ſurface, which may be here eſteemed as a kind of bark; and hence it muſt be conveyed to all the other parts. It is highly probable the juice which filled the cavities of the letters was brought thither from the bottom of the roots; nor is there any more difficulty in conceiving this than in comprehending how the ſap ſhould paſs from the roots of our largeſt oaks to the very extremities of their higheſt branches. Some ſtones, then (he concludes), muſt be allowed to vegetate and grow like plants: but this is not all; (he adds), that probably they are generated in the ſame manner; at leaſt, that there are abundance of ſtones whoſe generation is inconceivable, without ſuppoſing that they come from a kind of ſeeds, wherein the organical parts of the ſtones are wrapped up as thoſe of the largeſt plants are in their ſeeds.

Preliminary Processes.

ance, the other earths predominate; but if it remain in a powdery form, the aluminous earth is in greatest proportion. The oxides of different metals are indicated by the colour of the mass; when it is of a dark or brownish red, the metallic oxide is that of iron; a grass green colour denotes manganese; and yellowish green the oxide of chromium.

But there are some stones on which potash has a very feeble action, and in this case borax has been substituted for the alkali. This is the method which was followed by Mr Chenevix in analysing aluminous stones. A hundred grains of sapphire in powder were mixed with 250 grains of calcined borax, and subjected to a strong heat in a crucible of platina for two hours. When the mass was cold, it exhibited the appearance of a greenish blue glass, which adhered strongly to the crucible; but the whole being boiled for some hours in muriatic acid, it was completely dissolved; the earthy matter was then precipitated by means of sub-carbonate of ammonia, and the precipitate, after being well washed, was again dissolved in muriatic acid; and in this way the borax was separated. The remaining part of the analysis was nearly similar to that directed for other stones, excepting only that the alumina was separated from the potash by means of muriate of ammonia.

But to return to the examination and farther treatment of the mass in the silver crucible, which after being removed from the furnace, and wiped on the outside, is to be placed in a porcelain capsule; it is then filled with water, and this water is renewed occasionally, till the whole matter is separated from the crucible. By this means a part of the compound of the alkali with the siliceous and aluminous earths, is dissolved, and with a sufficient quantity of water, the whole may be dissolved. Muriatic acid is now to be added till the whole of the mass is brought to a state of solution. This, however, will not be the case, if the stone be composed chiefly of silica. On the first addition of the acid, a flakey precipitate is produced, because the acid unites with the alkali, which held the mass in solution. An effervescence afterwards takes place, which arises from the decomposition of a portion of carbonate of potash, formed during the fusion; and the flakey precipitate is again dissolved, as well as the matter which remained in the form of powder at the bottom of the vessel. If the powder be silica and alumina, there is no effervescence; but if it contain lime, an effervescence is produced. The solution in the muriatic acid being formed, if it shall appear colourless, it may be inferred that it contains no metallic oxide, or at least a very small portion. An orange red colour shews that it contains iron, a purplish red indicates manganese, and a golden yellow, chromium.

The solution is now to be introduced into an evaporating dish of porcelain, and being covered with paper, is to be placed on a sand bath, and evaporated to dryness. Towards the end of the evaporation, as the liquid assumes the form of a jelly, it must be constantly stirred with a rod of silver or porcelain, to permit the acid and water to pass off, and to allow the whole mass to be equally dried; for it is in this way that the silica and alumina are separated from each other. The matter being reduced to a dry powder, add to it a large quantity of pure water, expose it to a moderate heat, and pour it on a filter. This solution may be denominated A. Wash repeatedly the powder which remains upon the filter, till the water with which it is washed no longer precipitates silver from its solutions. The powder remaining is siliceous earth, which is first to be dried between folds of blotting paper, and then made red hot in a crucible of platina or silver; and when it is cold it is to be accurately weighed. If it be pure siliceous earth, it is in the form of a white powder, is of a white colour, does not adhere to the fingers, and is insoluble in acids. If it be at all coloured, it shews that it contains some metallic oxide, and is a proof that the evaporation has been carried on with too great a heat. To separate the oxide, boil the silica with an acid, and then wash and dry it as before. This acid solution is to be added to the solution A, and the whole is to be evaporated to about the quantity of an English pint; then add to it a solution of carbonate of potash, till the precipitation ceases; and it may be necessary to boil it a few moments, to allow the whole of the precipitate to fall to the bottom. The whole of the precipitate being collected at the bottom, the supernatant liquid is decanted off, and the water being put in its place, the precipitate and water are thrown on a filter; and when the water has run off, the filter with the precipitate upon it is placed on the folds of blotting paper. After the precipitate has acquired some degree of consistence, collect it carefully with an ivory knife, mix it with a solution of pure potash, and boil it in a capsule of porcelain. The potash dissolves the alumina or glucina, and the other substances remain in the form of a powder. This powder may be called B.

Add to the solution of potash as much acid as will saturate the potash, and also redissolve any precipitate which at first appeared; and then add carbonate of ammonia till the taste of it be perceptible in the liquid. The whole of the alumina is now precipitated in the form of white flakes, while the glucina remains dissolved, if a sufficient quantity of carbonate of ammonia had been employed. Filter the liquid; and the alumina remaining on the filter being washed and dried, and after being made red hot, and allowed to cool, is weighed. To prove its being alumina, dissolve it in sulphuric acid, and a sufficient quantity of sulphate or acetate of potash being added, the whole of it will be converted into alum crystals, if the earth employed be aluminous earth.

To separate the glucina, the liquid which passed through the filter is to be boiled for some time, and if the solution contain any of this earth it will be precipitated in the form of a light powder, which may be dried in the usual manner, and weighed. It is a fine, soft, light, tasteless powder, when in a state of purity; and the application of heat does not make it concrete, as happens to alumina.

We now return to the residuum B, in which may be expected lime, magnesia, and some of the metallic oxides. But if it be suspected that this residuum contains any yttria, it is to be treated with carbonate of ammonia, which dissolves the yttria, and leaves the other bodies untouched. The yttria being separated, the residuum B is to be dissolved in weak sulphuric acid, and the solution evaporated to dryness. Add a small quantity of water, which will dissolve the sulphate of magnesia, as well as the metallic sulphates; but the sulphate of lime remains undissolved, or if any part of it should dissolve, Preliminary Processes.

dissolve, it may be thrown down by adding a small portion of weak alcohol. After being made red hot in a crucible, it is to be weighed, and the lime will amount to $\frac{42}{100}$ of the weight. The solution containing the remaining sulphates being diluted with a large portion of water, a small excess of acid is to be added, and then a saturated carbonate of potash. The magnesia and oxide of manganese remain dissolved, and the oxides of chromium, iron, and nickel, are precipitated. This precipitate may be denominated C.

Add to the solution a solution of hydrosulphuret of potash, and the manganese in the state of a hydrosulphuret will be precipitated. Calcine the precipitate in contact with air, and weigh it. The addition of pure potash to the solution will precipitate the magnesia, which being washed, and subjected to a red heat, is also to be weighed.

The residuum C is to be repeatedly boiled with nitric acid, and then mixed with pure potash; and, being heated, the liquid is to be decanted off. The precipitate thus obtained, consisting of the oxides of iron and nickel, is to be washed with pure water, and this water is to be added to the solution of the nitric acid and potash. The chromium, if any be present, is contained in that solution, and is in the form of an acid. Add to the solution muriatic acid in excess, and let the evaporation be continued till the liquor become of a green colour; then add a pure alkali, by which the chromium is precipitated in the state of oxide, which is to be dried in the usual way, and weighed.

The precipitate containing the oxides of iron and nickel is to be dissolved in muriatic acid; ammonia is to be added in excess, when the oxide of iron precipitates; and being collected, washed and dried, is to be weighed. By evaporating the solution, the oxide of nickel will be also precipitated, or the whole may be precipitated by the addition of hydrosulphuret of ammonia. This being treated in the same manner as the other substances, is also to be weighed.

The weight of the whole substances thus obtained being added together, and being compared with the weight of the matter originally operated upon, if the two be equal, or if the difference do not exceed three or four parts in 100, it may be inferred that the analysis is nearly correct; but a considerable loss of weight indicates some error, and requires the analysis to be carefully repeated. If the same loss of weight appear, it may be concluded that the stone contained some substance which is soluble in water, or has been driven off by the heat. To ascertain the last point, a portion of the stone is to be broken into small pieces, and exposed to a strong heat, in a porcelain retort. If it contain water, or any volatile substance, it will come over into the receiver, and by this means the nature and weight of the ingredients separated may be ascertained. If nothing come over into the receiver, or if what is obtained be not equal to the deficient weight, it may be inferred that the stone contains some matter which is soluble in water.

A fixed alkali has been not unfrequently found in simple stones; and to ascertain whether the mineral subjected to analysis contains any alkaline matter, different methods have been pursued. These methods we shall now describe. The stone being reduced to an impalpable powder, is cautiously heated repeatedly with sulphuric acid, and the mass is to be digested in water; and this solution being properly concentrated, is set aside for some days. The appearance of crystals of alum is a certain indication that the mineral contained potash; and the quantity of potash may be estimated at $\frac{100}{1000}$ of the weight of those crystals; but if no crystals be obtained, the solution is to be evaporated to dryness, and the residuum exposed to a moderate red heat. Digest it afterwards in water, and add carbonate of ammonia, and filter; evaporate again to dryness, expose the residue to a heat of 700°, and redissolve it. The solution being properly concentrated, will give crystals of sulphate of soda or of potash, as the one or the other alkali is present. Potash may be discovered by adding to the solution of the salt, a solution of nitro-muriate of platina somewhat concentrated. A yellow precipitate, which is muriate of platina and potash, is thus obtained.

Klaproth's method for discovering fixed alkalies in minerals is the following. He takes four parts of nitrate of barytes to one of the mineral to be examined, and fuses them together in a porcelain crucible. A spongy mass of a light-blue colour was thus obtained, and with the addition of diluted muriatic acid, was completely dissolved. The solution, which was of a yellow colour, was then mixed with a sufficient quantity of sulphuric acid, by which the barytes is precipitated, and the muriatic acid expelled. The liquid is next evaporated to dryness, and the mass being digested in water, is filtered, and the sulphate of barytes and silica remain on the filter. The clear solution is saturated with carbonate of ammonia, and filtered a second time; and all the earthy and metallic bodies being separated, the sulphates of fixed alkali and ammonia only remain in the solution, which being evaporated to dryness, the dry saline mass is introduced into a porcelain crucible, and subjected to such a degree of heat as is sufficient to drive off the sulphate of ammonia. The residuum is then dissolved in water, and crystallized; and thus a pure, fixed alkaline sulphate is obtained, which is again dissolved in water, and decomposed, by adding acetate of barytes. The solution is then filtered, and the liquid is evaporated to dryness. The saline mass obtained is the acetate of a fixed alkali, which being exposed to heat in a crucible, became of a reddish colour. The carbonaceous residuum is then to be dissolved in water, filtered, and crystallized, and the salt thus procured is a carbonate of a fixed alkali, the nature of which may be easily recognised by the means stated above.

Mr Davy's method of detecting a fixed alkali in minerals, is different *. One hundred grains of the stone in very fine powder are to be fused for half an hour at a strong red heat, in a crucible of platina or silver, with 200 grains of boracic acid. An ounce and half of nitric acid diluted with seven or eight times its quantity of water, is then digested upon the fused mass, till the decomposition of the whole is completed. Evaporate the fluid to about two ounces, or one ounce and a half; by this means the siliceous earth is separated, which being collected on a filter, is to be washed with distilled water, till the boracic acid and the whole of the saline matter are separated. The fluid is then mixed with water that has passed through the filter, and evaporated to the quantity of half a pint, after which it is saturated with carbonate of ammonia, and boiled with an excess of this salt, till the whole of the substances capable of being

* Nichol. Journ. xiii. 86.

Zircon Genus.

being precipitated, have been thrown down. The ſolution being filtered, the earths and metallic oxides remain on the filter. Add nitric acid to the liquid till it acquire a ſtrong ſour taſte, and evaporate till the boracic acid appear free.

The fluid is then to be filtered, and evaporated to dryneſs, and the dry maſs being expoſed to a heat of about 450° Fahrenheit, the nitrate of ammonia is decompoſed, and the nitrate of potaſh or ſoda remains behind.

To detect fluoric acid, which has been ſometimes met with as a component part of ſtones, Klaproth heats the mineral with ſulphuric acid in a glaſs retort, the corroſion of which, and the depoſition of ſilica in the water of the receiver, are certain teſts of fluoric acid.

After the general obſervations which have now been offered, we proceed to give examples of the analyſis of minerals belonging to the different genera of earths and ſtones; and we ſhall follow the ſame order in which thoſe genera are deſcribed in the article MINERALOGY.

1. ZIRCON Genus.

The mineral affording the earth which characteriſes this genus, was analyſed by Klaproth in the following manner *. We ſelect that ſpecies which is called hyacinth.

* Eſſays, i. 195.

A. 100 grains of hyacinth being levigated in the flint-mortar, received an increaſe of weight of half a grain.

B. This pulverized hyacinth, digeſted with two ounces of nitro-muriatic acid, yielded, upon ſaturating the ſolution with potaſh, a light-brown precipitate, of three grains and a half, when dried. Ammonia, added to it, diſſolved nothing; and it remained colourleſs. After the precipitate had been again ſeparated from the volatile alkali, muriatic acid was added, which diſſolved its ferruginous contents, leaving a white earth behind, which, when ignited, weighed 1½ grain. The portion of iron, precipitated by cauſtic ammonia from the muriatic ſolution, weighed half a grain, when ignited, and became black and reſplendent. It was fuſed with a neutral phoſphate, upon charcoal, to find whether it contained mangaueſe; no trace was perceptible.

C. The above 1½ grains of earth B were now added again to the hyacinth, after treatment with acids. The ſtone was then ſubjected to red heat, with ſix times its quantity of cauſtic alkali, in the manner explained in the eſſay on the jargon of Ceylon; the ignited maſs was again liquefied with water; and the earth remaining after this proceſs weighed 123 grains, when collected, edulcorated, and dried.

D. The alkaline lixivium was then ſaturated with muriatic acid, and evaporated. At firſt it continued clear; but towards the end ſiliceous earth ſeparated, the quantity of which, after ignition, amounted to ſix grains.

E. To the 123 grains, previouſly well waſhed with water, a ſufficient quantity of muriatic acid was added; which, with the aſſiſtance of heat, diſſolved nearly the whole, a trifling reſidue excepted. This muriatic ſolution, evaporated in a moderate heat to a ſixth or eighth part, loſt its fluidity, and formed a limpid gelatinous coagulum. It was then covered with water, and expoſed, with repeated agitation, to a digeſting heat.

Siliceous Genus.

By this management, the ſiliceous earth ſeparated in ſlimy, intumeſced grains, and weighed, after ignition, 23¼ grains.

F. The ſolution, thus freed from its ſilica, was now ſaturated with a boiling ley of mild alkali; and the precipitate was waſhed and dried in the air. This laſt weighed 114 grains, proving, upon every trial, to be jargonic earth. A fourth part of it, heated to redneſs, weighed 16½ grains; which make the whole amount to 66 grains.

G. The above ſix grains D, with the 23¼ grains E, in the whole 29¼ grains of ſiliceous earth, were ignited with a quadruple weight of vegetable alkali. When this maſs had been again ſoftened with water, it left a reſidue, which was extracted by muriatic acid. From this muriatic ſolution, alſo, when ſaturated with potaſh, jargonic earth fell down, weighing four grains after ignition. Hence, ſubtracting theſe, the quantity of ſiliceous earth is reduced to 25¼ grains.

One hundred parts of hyacinth, therefore, have given

2. Of the SILICEOUS Genus.

A great proportion of the ſtones belonging to this genus are tranſparent, and have a vitreous appearance. They are ſo hard as to ſcratch glaſs, and, excepting the fluoric acid, they are not acted upon by acids. By fuſion with alkalies they form glaſs; they alſo enter into fuſion with boracic acid, and the acid of phoſphorus. Stones compoſed chiefly of pure ſilica, are tranſparent and colourleſs. When a mineral is preſented for examination, even if it poſſeſs moſt of the properties which characterize ſtones belonging to this genus, ſome preliminary proceſſes may be purſued to aſcertain farther its nature and component parts.

A. It is ſometimes difficult to reduce ſiliceous ſtones to a fine powder. To facilitate this operation, a a portion of the ſtone may be heated to redneſs, and in this ſtate ſuddenly plunged into cold water. If by the firſt heating it is not ſufficiently brittle, the operation may be repeated until the mineral can be reduced to a fine powder, as already directed.

B. One part of the ſtone in fine powder is now to be mixed with four or five parts of potaſh, diſſolved in the ſame quantity of water. The mixture is introduced into a ſilver crucible, and evaporated to dryneſs, ſtirring it conſtantly with a ſilver rod, according to the directions given above. The maſs being evaporated to dryneſs, the heat is to be gradually increaſed, till the crucible appears of a dull red heat, or till the maſs enter into quiet fuſion. In this ſtate it is kept for an hour.

C. Remove the crucible from the fire before it is completely cold; ſoften the maſs with water, by adding freſh

Siliceous Genus.

fresh portions from time to time, till the whole is detached from the crucible, and then add 12 times its bulk of water to effect a solution. If the stone consisted chiefly of siliceous earth, the greater part of the mass will be dissolved.

D. Add muriatic acid till no farther precipitate is effected, and without separating the precipitate, evaporate the whole to dryness.

E. Pour six times its bulk of muriatic acid, previously diluted with four parts of water, on the dry mass; boil the mixture for half an hour; let the insoluble part subside, and then collect it on a filter, and after being dried, subject it in a crucible to a red heat. This powder is the siliceous earth contained in the mineral.

But stones included under this genus contain very different proportions, not only of siliceous earth, but also of the other earths; and some of them even contain a far greater proportion of other earths than that which characterizes the genus under which they are arranged.

Analysis of Leucite.

The analysis of this mineral is particularly interesting, not only as Klaproth first detected in it potash, which was supposed to belong exclusively to the vegetable kingdom, and hence called vegetable alkali, but also as it places the skill and address of that eminent chemist in its examination in a very conspicuous light. The process was conducted in the following manner*.

* *Essays,* i. 348.

Ignited alone upon charcoal, the leucite is completely infusible. It undergoes no manner of alteration, and its splinters lose nothing of their lustre.

A small fragment, put into fused borax, is for a long time moved about in it before it dissolves, which it does by degrees; and the glass globule obtained is clear and light-brown.

By fusion with a neutral phosphate, the solution is still slower, and a colourless rifty glass pearl is produced.

One hundred grains of coarsely pounded leucite exposed for an hour to a strong red heat, in a small porcelain pot, lost of weight only one-eighth of a grain, and even the violent heat of the porcelain furnace produced in the leucite only an inconsiderable change.

A. One hundred grains of leucite, reduced to an impalpable powder, being several times digested in muriatic acid, dissolved a considerable part. A siliceous residue of 54 grains remained after ignition.

B. The siliceous earth ignited with twice its weight of caustic alkali, softened again with water, covered with muriatic acid, added to excess of saturation, and, after sufficient digestion with this last, being collected on the filter, and heated to redness, was found to have lost little of its weight.

C. Prussiate of potash added to the muriatic solution produced a precipitate which indicated one-eighth of a grain of oxide of iron.

D. The solution by caustic ammonia being decomposed, and the precipitate being separated, the remaining liquor was tried with carbonate of soda, but no farther change was effected.

E. The precipitate produced by means of pure ammonia D was first dried. It was next purified by digesting it with distilled vinegar, and afterwards neutralizing this acid by ammonia. It weighed 24 grains and a half, when edulcorated and ignited. Diluted sulphuric acid completely dissolved it to a limpid liquor, and when properly treated, the solution yielded only alum.

Siliceous Genus.

F. To obtain the earth, which possibly might have remained latent in the several washings, the whole were evaporated to dryness. After having re-dissolved the saline mass in water, the remaining portion of earth was collected, it amounted only to half a grain, and was siliceous earth.

There were therefore obtained,

Silica	- (A)	54		
——	- (F)	$\frac{1}{2}$		
		$54\frac{1}{2}$	-	54.50
Alumina	- (E)	-	-	24.50
				79
		Loss		21
				100

The remarkable loss of more than one-fifth of the whole weight of the mineral under examination, excited suspicion that some error had crept into the analysis, and led to a repetition of the experiments, by varying the processes as follows.

A. One hundred grains of leucite in fine powder were ignited for half an hour, with double their weight of caustic potash. To the mass softened with water muriatic acid was added, just to the point of saturation, and the mixture being filtered, the remaining undissolved residuum was washed and dried.

B. The mineral thus prepared for decomposition, was then treated with muriatic acid, and kept for some time at a boiling heat. By this process a quantity of silica separated, which after being heated to redness weighed 54 grains and a half.

C. Oxalate of potash being added to the muriatic solution, concentrated by evaporation, produced no turbidity. The alumina was separated by the same means as in the former experiments, and its weight amounted to nearly the same. By other trials it did not appear to have any mixture of other earths, and no other earth could be obtained by evaporating the waters with which the powders had been washed.

Thus, after varying the experiments, the same results were obtained, and the same loss still appeared. In the farther prosecution of this investigation, the following experiments were had recourse to.

A. Two hundred grains of leucite in fine powder were repeatedly digested with muriatic acid, and the siliceous earth collected on the filter, washed, and weighed after being red hot, amounted to 109 grains.

B. The muriatic solution was of a yellowish colour, and being reduced by evaporation in a sand heat to the consistence of honey, the surface appeared covered with a saline crust; and when completely cooled, the mass appeared like a thick clear oil, of a golden yellow colour, and full of crystals, some of which were of a cubical, and some of a tabular form. The yellow fluid was gently poured off, and the salt rinsed with small portions of alcohol. The solution diluted with alcohol was again evaporated, and the small portion of salt thus obtained

tained was again waſhed with alcohol, and added to the firſt. The whole of the ſalt being dried, weighed 70 grains. This was diſſolved in water, and ſome drops of a ſolution of ammonia being added, threw down ſome particles of alumina. The ſolution being cryſtallized in a warm place, yielded only cubical cryſtals, ſome of which were elongated to four-ſided columns.

C. That part of the muriatic ſolution which ſhot into cryſtals being diluted with water, and decompoſed in a boiling heat, by carbonate of ſoda, yielded a precipitate, which after waſhing, drying, and ignition, amounted to $47\frac{1}{2}$ grains of aluminous earth. Three times its weight of concentrated ſulphuric acid was added, and the mixture was evaporated nearly to dryneſs. The maſs was again diſſolved in water, and combined with a ſolution of acetate of potaſh, which being cryſtallized, produced only alum.

D. The ſiliceous earth A was mixed with double its weight of potaſh, and ſubjected to a ſtrong red heat for an hour. The maſs was reduced to powder, and diluted with water. Muriatic acid was added in exceſs, and digeſted with it. The filtered muriatic ſolution being ſaturated with ſoda yielded $1\frac{1}{2}$ grain of aluminous earth, after which there remained of ſilica $107\frac{1}{2}$ grains.

The 200 grains of leucite have thus afforded of

	grs.
Silica D	107.50
Alumina C	47.75
——— D	1.55
	156.75

Here there was ſtill a deficiency of 43.25 grains, to account for which the 70 grains of ſalt B muſt be examined. This examination was conducted in the following manner.

1. The taſte and figure of the cryſtals were found to be the ſame with thoſe of muriate of potaſh.

2. The ſolution produced no change in vegetable blues, or in reddened litmus paper.

3. When heated to redneſs, the ſalt made a crackling noiſe, and remained fixed in the fire.

4. Neither carbonate of ſoda nor cauſtic ammonia produced any turbidity in the ſolution.

5. Two parts of ſtrong ſulphuric acid were added to three of the ſalt, and the muriatic acid being driven off by heat, the maſs was again diſſolved in water, which afforded cryſtals of ſulphate of potaſh.

6. The remaining portion of ſalt was diſſolved in a ſmall quantity of water, and to this was added a concentrated ſolution of cryſtallized acid of tartar. The acidulous tartrate of potaſh (cream of tartar) was thus immediately produced and precipitated in the form of ſand. This was waſhed, dried, burnt in a ſilver crucible, and the coal obtained repeatedly waſhed with water. The ſolution being evaporated to dryneſs, after being examined by the proper teſts, appeared to be a carbonate of potaſh, which being ſaturated with nitric acid, afforded nitrate of potaſh.

Thus it appears that the baſe of the 70 grains of ſalt conſiſted entirely of pure potaſh, which was neutralized by part of the muriatic acid employed in decompoſing the mineral; and according to the proportion of baſe in muriate of potaſh, the 70 grains A contain 42.7 grains of alkali; and in this way the deficiency in the examination of the leucite is accounted for.

The reſult of the analyſis is as follows.

	grs.
Silica	53.75
Alumina	24.62
Potaſh	21.35
	129.72

Analyſis of Pitchſtone.

The pitchſtone which is the ſubject of the following analyſis, alſo conducted by Klaproth, is the tranſparent yellowiſh or olive green variety of that mineral from Meiſſen. It affords an example of ſoda, the other fixed alkali, forming a component part of ſtones.

A. 100 grains in coarſe fragments were introduced into a covered crucible, and were ſubjected to a red heat for half an hour. When taken from the fire they appeared of a white gray mixed with a yellowiſh colour, and having a rough feel, with ſomething of the appearance of glazing. They loſt $8\frac{1}{2}$ grains of weight.

B. In the heat of a porcelain furnace, the pitchſtone was fuſed both in the clay and charcoal crucible, and was converted into a clear glaſs, full of ſmall froth holes.

C. 100 grains of pitchſtone in fine powder were treated with a ſolution of 200 grains of cauſtic ſoda, and being put into a ſilver crucible, were kept for half an hour in a pretty ſtrong red heat. The maſs was then ſoftened with water; muriatic acid was added in exceſs; the ſolution was evaporated in a ſand heat, nearly to dryneſs; water was again poured upon it, after which it was filtered, and 73 grains of ſiliceous earth were obtained.

D. Cauſtic ſoda was mixed in exceſs with the muriatic ſolution, and the whole was digeſted in a boiling heat, by which the precipitate formed at the beginning of the proceſs was again diſſolved; a brown reſiduum ſtill remained, which being ſeparated, the alkaline ſolution was neutralized, and precipitated with carbonate of ſoda. The precipitate, which was alumina, after being waſhed, dried, and heated to redneſs, amounted to $14\frac{1}{2}$ grains. The whole of it yielded cryſtals of alum, with ſulphuric acid and potaſh.

E. The reſiduum which remained undiſſolved by the cauſtic ſoda D, was firſt diſſolved in muriatic, and then united with ſulphuric acid. Sulphate of lime was obtained, which was collected, and waſhed with diluted alcohol. By reducing the filtered fluid by evaporation to a ſmaller quantity, and combining it with ſulphuric acid, another portion of ſulphate of lime, which, added to the firſt, amounted to three grains, indicating 18 grains of pure lime.

F. The fluid was now freed from the calcareous earth; the iron which it contained was precipitated by carbonate of ammonia, which amounted to one grain. The remaining fluid was evaporated to dryneſs, and water being added to the ſaline reſiduum, fine minute flocks of oxide of mangancſe ſeparated, but in no greater quantity than one-tenth of a grain.

G. 100 grains of pitchſtone in powder were mixed with 300 grains of cryſtallized nitrate of barytes, and heated to redneſs in a porcelain veſſel, till the ſalt was entirely

Argillaceous Genus.

entirely decompofed. The cold mafs was foftened with water, neutralized with muriatic acid, and combined in fuch proportion with fulphuric acid, that the latter, after the evaporation of the mixture, and feparation of the muriatic acid by heat, was ftill in excefs. The mafs was wafhed with hot water; the refiduum feparated by filtration; and the clear fluid was mixed with carbonate of ammonia in excefs. The precipitate thus obtained was collected on a filter, and the remaining fluid was evaporated to drynefs, and the portion of fulphate of ammonia fubjected to a moderate heat in a porcelain veffel, was driven off. A fixed falt remained, which appeared to be fulphate of foda. This was rediffolved, and decompofed by acetate of barytes; the filtered folution was evaporated to drynefs; the dry falt was heated to rednefs in a crucible of platina. The faline refiduum being rediffolved, filtered, and again evaporated to drynefs, yielded three grains of dry carbonate of foda, indicating $1\frac{3}{4}$ grain of pure foda. This being neutralized with nitric acid, gave cryftals of nitrate of foda.

The 100 grains of the mineral thus examined confift of

3. Argillaceous Genus.

As many of the ftones included under this genus are compofed of fimilar fubftances with thofe arranged in the former genus, it is obvious that the examination is to be conducted in the fame way. We fhall therefore give one example of the analyfis of a ftone belonging to this genus, and the example is that of bafalt by Klaproth *.

* Effays, ii. 195.

Analyfis of Bafalt.

A. Small fragments of this ftone were fubjected to a ftrong red heat for 30 minutes; the lofs of weight was two per cent. and the mafs became of a lighter colour, and more readily yielded to the peftle.

B. Bafalt expofed to the heat of a porcelain furnace in a common clay crucible, fufed into a compact black brown glafs, which in thin fplinters was tranfparent. It alfo entered into thin fufion in a crucible of femi-indurated fteatites; part of it ran into the clefts produced in the fteatites, and the reft was found cryftallized in brown fhining lamellæ, which on the furface were ftriated, and cellularly concreted. In a charcoal crucible it was converted into a dull gray and finely porous mafs, in which were inferted numerous grains of iron.

C. To afcertain whether this ftone contained foda, 100 grains of bafalt in fine powder were mixed with 400 grains of nitrate of barytes, and were at firft expofed in a large porcelain veffel to a moderate heat, and afterwards to a heat gradually raifed to ignition. The mixture fwelled up, and when the heat was increafed, white fumes arofe on uncovering the veffel, which led to a fuppofition that the foda was beginning to volatilize. The fire was then removed.

Argillaceous Genus.

D. The porous mafs, after cooling and being reduced to powder, was drenched with water, and treated with muriatic acid. The whole entered into folution, and produced a clear yellow fluid. The folution was evaporated, and fulphuric acid was added gradually, till it was in excefs. The fulphate of barytes was precipitated.

E. The faline mafs by filtration was reduced to drynefs, and water was added, the fediment feparated, and appeared to confift of the fulphate of barytes, and the filiceous earth of the ftone. The clear fluid was faturated with ammonia, and the precipitate which was obtained being filtered off, the neutralized liquor was evaporated to drynefs, and then expofed in a porcelain veffel to a moderately intenfe heat, till the whole fulphate of ammonia was driven off. The fixed portion remaining diffolved in water, and cryftallized, appeared to be pure fulphate of foda. This was diffolved, decompofed by acetate of barytes; the precipitate, which was fulphate of barytes, was feparated by the filter, and the clear fluid being evaporated to drynefs, the dry acetate of foda was heated to rednefs in a crucible of platina; and in this way $4\frac{1}{2}$ grains of dry carbonate of foda was obtained, which is equal to 2.6 grains of pure foda.

F. To feparate the other ingredients, 100 grains of powdered bafalt were ignited for two hours with 400 grains of carbonate of foda, in a crucible of porcelain; but with a degree of heat which did not produce fufion. It united into a yellowifh, fomewhat hard mafs, which being reduced to powder, and foftened with water, was neutralized with muriatic acid. It was then a little fuperfaturated with nitric acid, and evaporated to drynefs. The colour of the dry mafs was faffron yellow. It was diffufed in water, flightly acidulated with muriatic acid, and after being digefted for a fhort time it was filtered. The filiceous earth collected on the filter was expofed to a red heat, and being weighed, amounted to $44\frac{1}{2}$ grains.

G. The muriatic folution being fufficiently diluted with water, was precipitated at the temperature of boiling water, by means of carbonate of foda. The precipitate being feparated, was digefted with a folution of cauftic foda, and a dark brown refiduum was feparated by filtration. Muriatic acid was added in a fmall excefs to the alkaline fluid, and this was precipitated with carbonate of ammonia. The precipitate obtained, after being wafhed and ignited, amounted to $16\frac{1}{4}$ grains. It yielded alum, when treated with fulphuric acid and potafh, and was therefore aluminous earth.

H. The brown refiduum G was diffolved in muriatic acid with particular attention to the precife point of faturation. Succinate of ammonia was added to the folution, to precipitate the iron; and the fuccinate of iron obtained, when perfectly wafhed and ftrongly heated in a covered crucible, afforded 20 grains of oxide of iron, which were attracted by the magnet.

I. The iron being feparated, the fluid was treated at the temperature of boiling with carbonate of foda; a white precipitate was obtained, which was diffolved in nitric acid; and fulphuric acid being combined with the folution, threw down fulphate of lime. This was feparated, and the remaining liquor being evaporated nearly

nearly to drynefs, was again diluted with a mixture of water and alcohol. Another portion of fulphate of lime fell down, which being feparated, was added to the former. The whole of the fulphate of lime was decompofed by boiling it with carbonate of foda in folution, and the carbonate of lime thus obtained, after being wafhed and dried, weighed 17 grains, indicating nine grains and a half of pure lime.

K. Upon the fluid left from the laft procefs, cauftic foda was affufed; a flimy precipitate was formed, which rapidly diffolved in fulphuric acid, and communicated a brown colour to the folution. It was evaporated in a fand bath; loofe brown flakes fell down at the commencement of the procefs, and thefe being feparated by the filter, appeared to be oxide of manganefe; the quantity eftimated did not exceed one-eighth of a grain.

L. The remaining portion of the fluid was evaporated to drynefs, and the refiduum was expofed in a fmall crucible to a ftrong red heat. It was again diffolved in water, and yielded a fmall portion of alumina coloured with iron, and contaminated with manganefe. After ignition it did not weigh more than half a grain; but the clear folution was entirely cryftallized, and afforded fulphate of magnefia. Carbonate of foda was added to the magnefian falt in folution, by which the earthy bafe was precipitated in the ftate of carbonate. It weighed fix grains, which is equal to $2\frac{1}{4}$ grains of pure magnefia.

The following is the refult of the preceding analyfis.

Silica F	44.5 grs.
Alumina G	16.25
——— I	.5
Oxide of iron H	20.
Lime I	9.5
Magnefia L	2.25
Oxide of manganefe K	.12
Soda E	2.60
Water A	2.
	97.72

4. Magnesian Genus.

Befides feveral of the earths detected in minerals belonging to the former genera, the ftones arranged under this genus are diftinguifhed by being combined with magnefia. We fhall only give one example of the analyfis of a magnefian ftone.

Analysis of Steatites.

This mineral, which was found in Cornwall, was analyzed by Klaproth in the following manner.

A. One ounce of the ftone in fmall pieces was fubjected to a ftrong red heat, by placing the glafs retort which contained it in an open fire. A fmall portion of water diftilled over, which was pure and taftelefs. The mineral loft 75 grains of its weight, and became darker in the colour, and confiderably harder.

B. After being reduced to powder, it was carefully mixed, and heated red hot, with two ounces of carbonate of potafh in a porcelain pot. The concreted mafs was levigated with water, and digefted with muriatic acid in excefs. A white loofe flimy earth was precipitated, which after being wafhed, dried, and fubjected to a red heat, weighed 204 grains. It was pure filica.

C. Pruffiate of potafh was added to the filtered folution, and produced a blue precipitate, which being collected, wafhed, dried, and ignited with a little wax, was found, after cooling, to weigh feven grains. The whole of it was attracted by the magnet. The portion of iron belonging to the pruffiate of potafh being fubtracted, left $3\frac{3}{4}$ grains of oxide of iron as a conftituent of the mineral under examination.

D. Carbonate of potafh being added to the folution freed from the iron, precipitated its earthy ingredient. This, after wafhing, and gentle ignition, weighed 192 grains. Thefe were covered with a proportionate quantity of concentrated diftilled vinegar, and being digefted in a low heat, were thrown upon the filter. The earth remaining on the paper, which, after being dried and heated red hot, weighed 93 grains, was mixed with three times its weight of ftrong fulphuric acid, and the mixture being evaporated in a fand heat nearly to drynefs, the dry mafs was diffolved in water and filtered; 26 grains of filiceous earth were thus obtained.

E. In the fulphuric folution D, there ftill remained 67 grains of earth, which being precipitated by an alkali, appeared to confift entirely of aluminous earth.

F. Ninety-nine grains of the firft, 192 grains of the earthy precipitate D, were taken up by the acetic acid, which being precipitated by carbonate of potafh, and the earth obtained being tried by fulphuric acid, was found to be pure magnefia.

This analyfis fhows that the 480 grains of fteatites thus examined, afforded

Silica B	204
—— D	26
Magnefia F	99
Alumina E	67
Oxide of iron C	3.75
Water A	75.
	474.75
Lofs	5.25
	480.00

or 100 parts of the mineral contain

Silica	48
Magnefia	20.5
Alumina	14.
Oxide of iron	1.
Water	15.5
	99.0

5. Calcareous Genus.

The analyfis of ftones belonging to this genus muft be varied according to the nature of the combination into which the lime has entered. With regard to the proceffes to be followed in the examination of calcareous ftones, they are fufceptible of a natural divifion into fuch as are foluble in muriatic or nitric acid with effervefcence, and fuch as are fcarcely foluble in thofe acids, and do not effervefce. To the firft belong all the ftones called limeftones, or carbonates of lime; and to the fecond belongs fulphate of lime, or gypfum.

Analysis of Carbonate of Lime.

Carbonate of lime, whether in the form of lime fpar, or in a lefs pure ftate, in the form of limeftone, is foluble with

Calcareous Genus

with effervescence in nitric or muriatic acid. When exposed to heat, it yields carbonic acid gas, and is converted into quicklime; and when fused with an alkali, does not form a uniform mass. But we shall give a short view of the processes to be followed in a more particular examination.

A. Let a determinate quantity of the stone be reduced to a fine powder. Digest it repeatedly with muriatic acid till no further action is produced upon it. Dilute the solution, throw it upon a filter, and, after drying, weigh the insoluble residuum.

B. Let the remaining solution be diluted with 24 times its bulk of water; add sulphuric acid diluted; a precipitate takes place if the stone contained any barytes, the amount of which, after being collected and dried, may be ascertained by weighing.

C. Add to the filtered solution, after the barytes has been separated, a solution of carbonate of soda, as long as any precipitate is formed. Collect this precipitate, and let it be so much dried that it may be easily removed from the filter.

D. Affuse the precipitate with sulphuric acid till all effervescence ceases.

E. Introduce the whole into a mixture of three parts of distilled water, and one of alcohol, in the proportion of eight parts of the mixture to the quantity of the substance previously dissolved in nitric acid. Let the whole be digested for some hours in the cold, filter the fluid, and dry the insoluble residuum and weigh it.

F. The remaining solution is next to be decomposed by a solution of carbonate of potash, and the precipitate being collected, is to be washed, dried, and weighed.

By this examination, if the stone is to be ranked with carbonate of lime, the weight of the insoluble part E, after subtracting from it one-third, must exceed the weight of the insoluble parts A and B.

Analysis of Sulphate of Lime.

As this is insoluble in nitric or muriatic acids, its analysis must be conducted in a different manner.

A. Let one part of the mineral, reduced to fine powder, be boiled with four times its weight of carbonate of potash, in a sufficient quantity of water for two or three hours; as the fluid evaporates, water is to be added.

B. Introduce the insoluble mass obtained by the last process into a flask containing diluted nitric acid, and the whole being dissolved, let it be evaporated to dryness, and weighed.

C. Add to the dried mass more than its own weight of strong sulphuric acid; apply heat, and let it be gradually increased till fumes cease to rise, and let it be again weighed.

D. Let the insoluble part be digested in twice its weight of cold water; filter the fluid, collect the insoluble residuum, and dry it in a dull red heat. To ascertain the quantity of lime, subtract from the weight of the insoluble mass left (in C) 59 parts; what remains is equal to the quantity of lime.

E. The quantity of lime also may be ascertained, by subjecting for some hours to a red heat, the insoluble mass B; for by this process it will be converted into quicklime.

Analysis of Fluate of Lime.

In the examination of this mineral, a quantity of it may be reduced to powder, and moistened with sulphuric acid, in a leaden or pewter vessel. The mixture being heated, fumes arise, to which a plate of glass being exposed, is soon corroded. In this way the fluoric acid may be detected, and the quantity of base may be ascertained by decomposing the mineral by means of sulphuric acid, and afterwards analysing the sulphate of lime, as already directed.

Analysis of Phosphate of Lime.

The analysis of this mineral may be conducted in the following manner.

A. Let a determinate portion be digested in five times its quantity of muriatic acid, and let the operation be repeated till the acid has no farther action upon the residuum; decant the fluid, and then let it be diluted with water and filtered.

B. Add to the muriatic solution, liquid ammonia; collect the precipitate which is formed, and after being washed and dried, expose it to heat.

C. Add nitric acid to the precipitate till the whole is dissolved. Precipitate again by means of sulphuric acid; let the whole then be filtered, and let the insoluble residuum be washed with as little water as possible.

D. Evaporate the filtered fluid to the consistence of syrup; the fluid thus obtained is phosphoric acid, if the stone examined have been phosphate of lime. The test of phosphoric acid is, that it precipitates lime water, and also forms precipitates with the solutions of sulphate of iron, and nitrate of mercury; but it does not precipitate the muriate or nitrate of barytes.

6. Barytic Genus.

Analysis of Carbonate of Barytes.

A. Take a determinate quantity of the mineral, and dissolve it in diluted nitric acid; take a portion of the solution, and add to it a solution of sulphate of soda. If a precipitate take place, by adding a small quantity of the salt to the solution of the earth, diluted with 24 times its bulk of water, it may be inferred that the base of the mineral is barytes.

B. Let the nitric solution be evaporated to dryness, and exposed in a silver crucible to a white heat; the earth obtained is barytes, which is soluble in 20 times its weight of water; and after evaporation, crystallizes into long four-sided prisms.

Analysis of Sulphate of Barytes.

This mineral was analyzed by Klaproth in the following manner.

A. 200 grains were mixed with 500 grains of carbonate of potash, and were exposed for two hours to a red heat; the mass was reduced to powder, boiled with water, and the undissolved earth was collected on the filter.

B. To separate the siliceous earth, the fluid was neutralised by muriatic acid, and evaporated to dryness. The saline mass was redissolved in water, and the silica remaining after being ignited, weighed 18 grains.

C. The barytic earth, freed from the sulphuric acid B, was covered with water; muriatic acid was added; the whole was dissolved by digestion, except two grains of silica. The filtered solution was crystallized, and afforded muriate of barytes.

D. The crystals were redissolved in water, and sulphuric acid was added to the solution, while any precipitate appeared, and the regenerated sulphate of barytes being

Barytic Genus.

being washed and dried, weighed 185 grains, but after ignition, only 180 grains.

One hundred parts of this mineral are therefore composed of

Sulphate of barytes D	90
Silica B	9
—— C	1
	100 *

* Essays, i. 375.

7. Strontian Genus.

Analysis of Carbonate of Strontites.

This mineral was analyzed by Klaproth, in the following manner.

A. 100 parts were dissolved in muriatic acid, diluted with half its quantity of water. Thirty parts of carbonic acid were driven off during the solution, which being evaporated, afforded crystals in the shape of needles; and these crystals being dissolved in alcohol, communicated to it the property of burning with a carmine red flame. This is the test of strontitic earth.

B. To ascertain whether the mineral examined contained any barytes, three drops of a solution of one grain of sulphate of potash in six ounces of water were added to the muriatic solution; no appearance of precipitate was observed till next day, and therefore it contained no barytes, as in that case an immediate precipitate would have taken place.

C. Carbonate of potash was then added to the muriatic solution; a decomposition took place; and the carbonate of strontites was precipitated. This being subjected to a strong heat, the carbonic acid was driven off, and the whole of the remaining earth being dissolved in water, crystallized. After being dried, it weighed 69.5.

One hundred parts of this mineral therefore contain

Pure earth	69.5
Carbonic acid	30.
Water	.5
	100.0 †

† Ibid. i. 231.

II. Salts.

The analysis of minerals arranged under this class, is in general less difficult, in consequence of their easy solubility, than those already examined. We shall therefore give only one example.

Analysis of Native Saltpetre.

This native salt was examined by Klaproth ‡, according to the following method.

‡ Ibid. i. 270.

A. 1000 grains of the native salt, with limestone and gypsum to which it adhered, were covered with boiling water. The colourless solution was gently evaporated; during the crystallization, tender needle-shaped crystals of selenite appeared, and the whole of the solution crystallized to a perfect prismatic nitre. The selenite weighed 40 grains, and the salt amounted to 446 grains.

B. To ascertain whether any common salt could be detected in the mineral, the crystals were redissolved in water, and acetate of barytes was dropt into the solution. A precipitate was obtained, amounting to 26 grains of sulphate of barytes, shewing that 18½ grains of selenite were still combined with the neutral salt. A solution of nitrate of silver was added to the nitric solution, which produced a precipitate of 4½ grains of muriate of silver, so that the quantity of common salt can only be estimated at two grains. The pure nitre is thus reduced to 425½ grains. Klaproth suspects that the neutral muriate mixed with the native nitre, is rather a muriate of potash, than muriate of soda.

Salts.

C. The stony matters remaining amounted to 500 grains; muriatic acid was poured upon them, and produced great effervescence with pieces of limestone. One hundred and eighty-six grains of white gypsum remained; and the sulphuric acid being separated from it, by boiling with carbonate of potash, the carbonate of lime remaining behind dissolved without residuum in nitric acid.

D. The limestone taken up by the muriatic acid, weighed 304 grains. Being farther examined, it appeared to be calcareous earth, slightly contaminated with iron.

One hundred parts, therefore, of this salt contain

Pure prismatic nitre B	42.55
Muriate of a neutral salt B	.20
Sulphate of lime A B C	25.45
Carbonate of lime D	30.4
Loss	1.4
	100.00

III. Combustibles.

Analysis of Coal.

The constituent parts of coal are carbone and bitumen, with some earthy matters, and sometimes a small quantity of metallic matter. The proportion of earthy matters contained in coal may be ascertained by weighing a determinate quantity, and burning it. The nature of the earths contained in the residuum may be discovered by the processes already given.

To ascertain the proportion of charcoal and bitumen contained in coal, we shall describe the method followed by Mr Kirwan.

It has been found that a certain proportion of carbone or pure charcoal, detonated with nitre in the state of ignition, decomposes a given proportion of that salt; and it appears from the experiments of Lavoisier, that 13.21 parts of charcoal decompose 100 parts of nitre, while the detonation is performed in close vessels; but in an open crucible, a smaller proportion of charcoal is required, in consequence of part of the nitre being decomposed by the action of the air of the atmosphere. According to Kirwan, about 10 parts of charcoal are sufficient to decompose 96 parts of nitre. Mr Kirwan also found that vegetable pitch and maltha did not produce any detonation with nitre, but merely burnt on its surface; and that the same quantity of charcoal was required for the decomposition of the nitre, as if no bituminous substance had been employed. Since, therefore, bitumen produces no effect in decomposing nitre, Kirwan thought that the proportion of charcoal, in any coal, might be ascertained by detonation with nitre. In this way the proportion of carbonaceous and earthy matter in any coal being discovered, the proportion of bitumen which it contains may be estimated by calculation.

In the experiments on the analysis of coal, Mr Kirwan employed a large crucible placed in a wind furnace, and exposed to an equable heat. The coal was reduced to small

Combustibles.

small pieces of the size of a pin head, and was projected in portions of one or two grains at a time, into the nitre, the moment it became red hot. This was continued till the detonation ceased.

By this process it appeared that 50 grains of Kilkenny coal were necessary to decompose 480 grains of nitre. According to the same proportion, 96 grains of nitre would have required for its decomposition 10 grains of coal, which is exactly equal to the quantity of charcoal that would have been required to produce the same effect; and thus it appeared that Kilkenny coal is almost entirely composed of carbonaceous matter.

In the examination of cannel coal, Mr Kirwan burnt 240 grains, till the whole of the carbonaceous matter was consumed; a residuum of seven grains and a half of reddish brown ashes, which appeared to be chiefly aluminous earth, was left, or about 3.12 per cent. Sixty-six grains and a half of this coal were found necessary to decompose 480 grains of nitre. Fifty grains of charcoal would have produced the same effect, and hence $66\frac{1}{2}$ grains of coal contain 50 of charcoal, and 2.08 parts of ashes, which being subtracted from $66\frac{1}{2}$ grains, leaves 14.42 for the quantity of bitumen contained in the coal. Hence the constituent parts of this coal are,

Charcoal	75.2
Bitumen	21.68
Ashes	3.1
	99.98

For a more particular analysis of combustible minerals, see Mr Hatchett's experiments, detailed in the Philosophical Transactions for 1804.

IV. *Analysis of* Soils.

The examination of soils is by no means the least important, because on a knowledge of the nature and proportions of the ingredients which enter into the composition of soils, depends the opinion to be formed of their fertility. Soils consist of different combinations of the earths, mixed with a certain proportion of animal and vegetable matter. The investigation of the nature of soils has been particularly prosecuted by Mr Kirwan * and Mr Davy. From the observations of the latter, the following account of the analysis of soils is extracted.

* See his *Treatise on Manures.*

1 Instruments for the analysis of soils.

1. The really important instruments required for the analysis of soils are few, and but little expensive. They are, a balance capable of containing a quarter of a pound of common soil, and capable of turning when loaded with a grain; and a series of weights from a quarter of a pound troy to a grain; a wire sieve, sufficiently coarse to admit a pepper-corn through its apertures; an Argand lamp and stand; some glass bottles; Hessian crucibles; porcelain or queen's ware evaporating basons; a Wedgewood pestle and mortar; some filters made of half a sheet of blotting paper, folded so as to contain a pint of liquid, and greased at the edges; a bone knife, and an apparatus for collecting and measuring aëriform fluids.

The chemical substances or reagents required for separating the constituent parts of the soil, are muriatic acid (spirit of salt), sulphuric acid, and pure volatile alkali dissolved in water, solution of prussiate of potash, soap lye, solution of carbonate of ammonia, of muriate of ammonia, solution of neutral carbonate of potash, and nitrate of ammonia.

Soils.

2 Mode of collecting soils for analysis.

2. In cases when the general nature of the soil of a field is to be ascertained, specimens of it should be taken from different places, two or three inches below the surface, and examined as to the similarity of their properties. It sometimes happens, that upon plains the whole of the upper stratum of the land is of the same kind, and in this case one analysis will be sufficient; but in valleys, and near the beds of rivers, there are very great differences, and it now and then occurs that one part of a field is calcareous, and another part siliceous; and in this case, and in analogous cases, the portions different from each other should be separately submitted to experiment.

Soils, when collected, if they cannot be immediately examined, should be preserved in phials quite filled with them, and closed with ground glass stoppers.

The quantity of soil most convenient for a perfect analysis is from two to four hundred grains. It should be collected in dry weather, and exposed to the atmosphere till it becomes dry to the touch.

The specific gravity of a soil, or the relation of its weight to that of water, may be ascertained by introducing into a phial, which will contain a known quantity of water, equal volumes of water and of soil; and this may be easily done by pouring in water till it is half full, and then adding the soil till the fluid rises to the mouth; the difference between the weight of the soil and that of the water will give the result. Thus, if the bottle contain 400 grains of water, and gains 200 grains when half filled with water and half with soil, the specific gravity of the soil will be two, that is, it will be twice as heavy as water; and if it gained 165 grains, its specific gravity would be 1825, water being 1000.

It is of importance that the specific gravity of a soil should be known, as it affords an indication of the quantity of animal and vegetable matter it contains; these substances being always most abundant in the lighter soils.

The other physical properties of soils should likewise be examined before the analysis is made, as they denote, to a certain extent, their composition, and serve as guides in directing the experiments. Thus, siliceous soils are generally rough to the touch, and scratch glass when rubbed upon it; aluminous soils adhere strongly to the tongue, and emit a strong earthy smell when breathed on; and calcareous soils are soft, and much less adhesive than aluminous soils.

3 Mode of ascertaining the quantity of water absorbed by soils.

3. Soils, though as dry as they can be made by continued exposure to air, in all cases still contain a considerable quantity of water, which adheres with great obstinacy to the earths and animal and vegetable matter, and can only be driven off from them by a considerable degree of heat. The first process of analysis is, to free the given weight of the soil from as much of this water as possible, without, in other respects, affecting its composition; and this may be done by heating it for ten or twelve minutes over an Argand's lamp, in a bason of porcelain, to a temperature equal to 300 Fahrenheit; and in case a thermometer is not used, the proper degree may be easily ascertained, by keeping a piece of wood in contact with the bottom of the dish: as long as the colour of the wood remains unaltered, the heat is not too high; but when the wood begins to be charred, the process must be stopped. A small quantity of water will perhaps remain in the soil even after this operation, but

but it always affords ufeful comparative refults; and if a higher temperature were employed, the vegetable or animal matter would undergo decompofition, and in confequence the experiment be wholly unfatisfactory.

The lofs of weight in the procefs fhould be carefully noted; and when in 400 grains of foil it reaches as high as 50, the foil may be confidered as in the greateft degree abforbent, and retentive of water, and will generally be found to contain a large proportion of aluminous earth. When the lofs is only from 20 to 10, the land may be confidered as only flightly abforbent and retentive, and the filiceous earth as moft abundant.

4 Separation of ftones, &c.

4. None of the loofe ftones, gravel, or large vegetable fibres fhould be divided from the pure foil till after the water is drawn off; for thefe bodies are themfelves often highly abforbent and retentive, and in confequence influence the fertility of the land. The next procefs, however, after that of heating, fhould be their feparation, which may be eafily accomplifhed by the fieve, after the foil has been gently bruifed in a mortar. The weights of the vegetable fibres or wood, and of the gravel and ftones, fhould be feparately noted down, and the nature of the laft afcertained: if calcareous, they will effervefce with acids; if filiceous, they will be fufficiently hard to fcratch glafs; and if of the common aluminous clafs of ftones, they will be foft, eafily fcratched with a knife, and incapable of effervefcing with acids.

5 Separation of the fand and clay, or loam, from each other.

5. The greater number of foils, befides gravel and ftones, contain larger or fmaller proportions of fand of different degrees of finenefs; and it is a neceffary operation, the next in the procefs of analyfis, to detach them from the parts in a ftate of more minute divifion, fuch as clay, loam, marle, and vegetable and animal matter. This may be effected in a way fufficiently accurate, by agitation of the foil in water. In this cafe, the coarfe fand will generally feparate in a minute, and the finer in two or three minutes; whilft the minutely divided animal or vegetable matter will remain in a ftate of mechanical fufpenfion for a much longer time; fo that, by pouring the water from the bottom of the veffel, after one, two, or three minutes, the fand will be principally feparated from the other fubftances, which, with the water containing them, muft be poured into a filter, and, after the water has paffed through, collected, dried, and weighed. The fand muft likewife be weighed, and their refpective quantities noted down. The water of lixiviation muft be preferved, as it will be found to contain the faline matter, and the foluble animal or vegetable matters, if any exift in the foil.

6 Examination of the fand.

6. By the procefs of wafhing and filtration, the foil is feparated into two portions, the moft important of which is generally the finely divided matter. A minute analyfis of the fand is feldom or never neceffary, and its nature may be detected in the fame manner as that of the ftones or gravel. It is always either filiceous fand, or calcareous fand, or a mixture of both. If it confift wholly of carbonate of lime, it will be rapidly foluble in muriatic acid, with effervefcence; but if it confift partly of this fubftance, and partly of filiceous matter, the refpective quantities may be afcertained by weighing the refiduum after the action of the acid, which muft be applied till the mixture has acquired a four tafte, and has ceafed to effervefce. This refiduum is the filiceous part; it muft be wafhed, dried, and heated ftrongly in a crucible: the difference between the weight of the whole, indicates the proportion of calcareous fand.

7 Examination of the finely divided matter of foils, and mode of detecting mild lime and magnefia.

7. The finely divided matter of the foil is ufually very compound in its nature; it fometimes contains all the four primitive earths of foils, as well as animal and vegetable matter; and to afcertain the proportions of thefe with tolerable accuracy, is the moft difficult part of the fubject.

The first procefs to be performed, in this part of the analyfis, is the expofure of the fine matter of the foil to the action of the muriatic acid. This fubftance fhould be poured upon the earthy matter in an evaporating bafon, in a quantity equal to twice the weight of the earthy matter; but diluted with double its volume of water. The mixture fhould be often ftirred, and fuffered to remain for an hour or an hour and a half before it is examined.

If any carbonate of lime or of magnefia exift in the foil, they will have been diffolved in this time by the acid, which fometimes takes up likewife a little oxide of iron; but very feldom any alumina.

The fluid fhould be paffed through a filter; the folid matter collected, wafhed with rain water, dried at a moderate heat, and weighed. Its lofs will denote the quantity of folid matter taken up. The wafhings muft be added to the folution; which, if not four to the tafte, muft be made fo by the addition of frefh acid, when a little folution of common pruffiate of potafh muft be mixed with the whole. If a blue precipitate occur, it denotes the prefence of oxide of iron, and the folution of the pruffiate muft be dropped in till no further effect is produced. To afcertain its quantity, it muft be collected in the fame manner as other folid precipitates, and heated: the refult is oxide of iron.

Into the fluid freed from oxide of iron, a folution of neutralized carbonate of potafh muft be poured till all effervefcence ceafes in it, and till its tafte and fmell indicate a confiderable excefs of alkaline falt.

The precipitate that falls down is carbonate of lime; it muft be collected on the filter, and dried at a heat below that of rednefs.

The remaining fluid muft be boiled for a quarter of an hour, when the magnefia, if any exift, will be precipitated from it, combined with carbonic acid, and its quantity is to be afcertained in the fame manner as that of the carbonate of lime.

If any minute proportion of alumina fhould, from peculiar circumftances, be diffolved by the acid, it will be found in the precipitate with the carbonate of lime, and it may be feparated from it by boiling for a few minutes with foap lye, fufficient to cover the folid matter. This fubftance diffolves alumina, without acting upon carbonate of lime.

Should the finely divided foil be fufficiently calcareous to effervefce very ftrongly with acids, a very fimple method may be adopted for afcertaining the quantity of carbonate of lime, and one fufficiently accurate in all common cafes.

Carbonate of lime, in all its ftates, contains a determinate proportion of carbonic acid, *i. e.* about 45 per cent.; fo that when the quantity of this elaftic fluid, given out by any foil during the folution of its calcareous matter in an acid, is known, either in weight or meafure, the quantity of carbonate of lime may be eafily difcovered.

When

Soils.

When the proceſs by diminution of weight is employed, two parts of the acid and one part of the matter of the ſoil muſt be weighed in two ſeparate bottles, and very ſlowly mixed together till the effervefcence ceaſes; the difference between their weight before and after the experiment denotes the quantity of carbonic acid loſt; for every four grains and a half of which, ten grains of carbonate of lime muſt be eſtimated.

The beſt method of collecting the carbonic acid, ſo as to diſcover its volume, is by the pneumatic apparatus, the conſtruction and application of which are deſcribed at the end of this article. The eſtimation is, for every ounce meaſure of carbonic acid, two grains of carbonate of lime.

8 Mode of aſcertaining the quantity of inſoluble finely divided animal and vegetable matter.

8. After the fine matter of the ſoil has been acted upon by muriatic acid, the next proceſs is to aſcertain the quantity of finely divided inſoluble animal and vegetable matter that it contains.

This may be done with ſufficient preciſion, by heating it to ſtrong ignition in a crucible over a common fire till no blackneſs remains in the maſs. It ſhould be often ſtirred with a metallic wire, ſo as to expoſe new ſurfaces continually to the air; the loſs of weight that it undergoes denotes the quantity of the ſubſtance that it contains deſtructible by fire and air.

It is not poſſible to aſcertain whether this ſubſtance is wholly animal or vegetable matter, or a mixture of both. When the ſmell emitted during the incineration is ſimilar to that of burnt feathers, it is a certain indication of ſome animal matter; and a copious blue flame at the time of ignition almoſt always denotes a conſiderable proportion of vegetable matter. In caſes when the experiment is needed to be very quickly performed, the deſtruction of the decompoſable ſubſtances may be aſſiſted by the agency of nitrate of ammonia, which, at the time of ignition, may be thrown gradually upon the heated maſs, in the quantity of twenty grains for every hundred of reſidual oil. It affords the principle neceſſary to the combuſtion of the animal and vegetable matter, which it cauſes to be converted into elaſtic fluids; and it is itſelf at the ſame time decompoſed and loſt.

9 Mode of ſeparating aluminous and ſiliceous matter and oxide of iron.

9. The ſubſtances remaining after the decompoſition of the vegetable and animal matter, are generally minute particles of earthy matter containing uſually alumina and ſilica with combined oxide of iron.

To ſeparate theſe from each other, the ſolid matter ſhould be boiled for two or three hours with ſulphuric acid, diluted with four times its weight of water; the quantity of the acid ſhould be regulated by the quantity of ſolid reſiduum to be acted on, allowing for every hundred grains two drachms or one hundred and twenty grains of acid.

The ſubſtance remaining after the action of the acid may be conſidered as ſiliceous; and it muſt be ſeparated and its weight aſcertained, after waſhing and drying in the uſual manner.

The alumina and the oxide of iron, if they exiſt, are both diſſolved by the ſulphuric acid; they may be ſeparated by carbonate of ammonia, added to exceſs; it throws down the alumina, and leaves the oxide of iron in ſolution; and this ſubſtance may be ſeparated from the liquid by boiling.

Should any magneſia and lime have eſcaped ſolution in the muriatic acid, they will be found in the ſulphuric acid; this, however, is ſcarcely ever the caſe; but the proceſs for detecting them, and aſcertaining their quantities, is the ſame in both inſtances.

The method of analyſis by ſulphuric acid is ſufficiently preciſe for all uſual experiments; but if very great accuracy be an object, dry carbonate of potaſh muſt be employed as the agent, and the reſiduum of the incineration muſt be heated red for half an hour, with four times its weight of this ſubſtance, in a crucible of ſilver, or of well baked porcelain. The maſs obtained muſt be diſſolved in muriatic acid, and the ſolution evaporated till it is nearly ſolid; diſtilled water muſt then be added, by which the oxide of iron and all the earths, except ſilica, will be diſſolved in combination as muriates. The ſilex, after the uſual proceſs of lixiviation, muſt be heated red; the other ſubſtances may be ſeparated in the ſame manner as from the muriatic and ſulphuric ſolutions.

10 Mode of diſcovering ſoluble animal and vegetable matter, and ſaline matter.

10. If any ſaline matter, or ſoluble vegetable or animal matter, be ſuſpected in the ſoil, it will be found in the water of lixiviation uſed for ſeparating the ſand.

This water muſt be evaporated to dryneſs in an appropriate diſh, at a heat below its boiling point.

If the ſolid matter obtained is of a brown colour and inflammable, it may be conſidered as partly vegetable extract. If its ſmell, when expoſed to heat, be ſtrong and fœtid, it contains animal mucilaginous or gelatinous ſubſtance; if it be white and tranſparent, it may be conſidered as principally ſaline matter. Nitrate of potaſh (nitre), or nitrate of lime, is indicated in this ſaline matter, by its detonating with a burning coal. Sulphate of magneſia may be detected by its bitter taſte; and ſulphate of potaſh produces no alteration in ſolution of carbonate of ammonia, but precipitates ſolution of muriate of barytes.

11 Mode of detecting ſulphate of lime (gypſum) and phoſphate of lime in ſoils.

11. Should ſulphate or phoſphate of lime be ſuſpected in the entire ſoil, the detection of them requires a particular proceſs upon it. A given weight of it, for inſtance four hundred grains, muſt be heated red for half an hour in a crucible, mixed with one third of powdered charcoal. The mixture muſt be boiled for a quarter of an hour, in a half-pint of water, and the fluid collected through the filter, and expoſed for ſome days to the atmoſphere in an open veſſel. If any ſoluble quantity of ſulphate of lime (gypſum) exiſted in the ſoil, a white precipitate will gradually form in the fluid, and the weight of it will indicate the proportion.

Phoſphate of lime, if any exiſt, may be ſeparated from the ſoil after the proceſs for gypſum. Muriatic acid muſt be digeſted upon the ſoil, in quantity more than ſufficient to ſaturate the ſoluble earths; the ſolution muſt be evaporated, and water poured upon the ſolid matter. This fluid will diſſolve the compounds of earths with the muriatic acid, and leave the phoſphate of lime untouched.

12 Reſults and products.

12. When the examination of a ſoil is completed, the products ſhould be claſſed, and their quantities added together; and if they nearly equal the original quantity of ſoil, the analyſis may be conſidered as accurate. It muſt however be noticed, that when phoſphate or ſulphate of lime is diſcovered by the independent proceſs 11. a correction muſt be made for the general proceſs, by ſubtracting a ſum equal to their weight from the quantity of carbonate of lime obtained by precipitation from the muriatic acid.

In arranging the products, the form ſhould be in the order

Soils.

order of the experiments by which they were obtained.

Thus, 400 grains of a good siliceous sandy soil may be supposed to contain

Of water of absorption - -	18 grs.
Of loose stones and gravel, principally siliceous, - -	42
Of undecompounded vegetable fibres	10
Of fine siliceous sand - -	200
Of minutely divided matter separated by filtration, and consisting of	
Carbonate of lime - -	25
Carbonate of magnesia - -	4
Matter destructible by heat, principally vegetable, - -	10
Silica - - - - - -	40
Alumina - - - - -	32
Oxide of iron - - - -	4
Soluble matter, principally sulphate of potash and vegetable extract, - -	5
Gypsum - - - - -	3
Phosphate of lime - -	2
Amount of all the products	395
Loss - - - -	5

In this instance the loss is supposed small; but in general, in actual experiments, it will be found much greater, in consequence of the difficulty of collecting the whole quantities of the different precipitates; and when it is within thirty for four hundred grains, there is no reason to suspect any want of due precision in the processes.

13 Chemical composition of fertile corn soils in this climate.

13. A very fertile corn soil from Ormiston in East Lothian afforded, in 100 parts, only 11 parts of mild calcareous earth; it contained 25 parts of siliceous sand: the finely divided clay amounted to 45 parts. It lost nine in decomposed animal and vegetable matter, and four in water, and afforded indications of a small quantity of phosphate of lime.

This soil was of a very fine texture, and contained very few stones or vegetable fibres. It is not unlikely that its fertility was in some measure connected with the phosphate; for this substance is found in wheat, oats, and barley, and may be a part of their food.

A soil from the low lands of Somersetshire, celebrated for producing excellent crops of wheat and beans without manure, was found to consist of one-ninth of sand, chiefly siliceous, and eight-ninths of calcareous marl tinged with iron, and containing about five parts in 100 of vegetable matter. No phosphate or sulphate of lime could be detected in it; so that its fertility must have depended principally upon its power of attracting principles of vegetable nourishment from water and the atmosphere.

14 Composition of soils proper for bulbous roots and for trees.

Mr Tillet, in some experiments made on the composition of soils at Paris, found that a soil composed of three-eighths of clay, two-eighths of river sand, and three-eighths of the parings of limestone, was very proper for wheat.

14. In general, bulbous roots require a soil much more sandy and less absorbent than the grasses. A very good potato soil, from Varsel in Cornwall, afforded seven-eighths of siliceous sand; and its absorbent power was so small, that 100 parts lost only two by drying at 400 Fahrenheit.

Plants and trees, the roots of which are fibrous and hard, and capable of penetrating deep into the earth, will vegetate to advantage in almost all common soils which are moderately dry, and which do not contain a very great excess of vegetable matter.

The soil taken from a field at Sheffield-place in Sussex, remarkable for producing flourishing oaks, was found to consist of six parts of sand, and one part of clay and finely divided matter. And 100 parts of the entire soil, submitted to analysis, produced

Water - -	3 parts
Silica - - -	54
Alumina - - - -	28
Carbonate of lime - -	3
Oxide of iron - -	5
Decomposing vegetable matter	4
Loss - - -	3

15 Improvements made by changing the composition of the earthy parts of soils.

15. From the great difference of the causes that influence the productiveness of lands, it is obvious that, in the present state of science, no certain system can be devised for their improvement, independent of experiment: but there are few cases in which the labour of analytical trials will not be amply repaid by the certainty with which they denote the best methods of amelioration; and this will particularly happen when the defect of composition is found in the proportions of the primitive earths.

In supplying animal or vegetable manure, a temporary food only is provided for plants, which is in all cases exhausted by means of a certain number of crops; but when a soil is rendered of the best possible constitution and texture, with regard to its earthy parts, its fertility may be considered as permanently established. It becomes capable of attracting a very large portion of vegetable nourishment from the atmosphere, and of producing its crops with comparatively little labour and expence.

Description of the Apparatus for the Analysis of Soils. Plate DIX.

A, Retort.

B, B, Funnels for the purpose of filtrating.

D, Balance.

E, Argand's lamp.

F, G, H, K, The different parts of the apparatus required for measuring the quantity of elastic fluid given out during the action of an acid on calcareous soils.

F, Represents the bottle for containing the soil.

K, The bottle containing the acid furnished with a stopcock.

G, The tube connected with a flaccid bladder.

I, The graduated measure.

H, The bottle for containing the bladder. When this instrument is used, a given quantity of soil is introduced into F; K is filled with muriatic acid diluted with an equal quantity of water; and the stopcock being closed is connected with the upper orifice of F, which is ground to receive it. The tube G is introduced into the lower orifice of F, and the bladder connected with it placed in its flaccid state into H, which is filled with water. The graduated measure is placed under the tube of H. When the stopcock of K is turned,

Soils.

ed, the acid flows into F, and acts upon the soil; the elastic fluid generated passes through G into the bladder, and displaces a quantity of water in H equal to it in bulk, and this water flows through the tube into the graduated measure; the water in which gives by its volume the indication of the proportion of carbonic acid disengaged from the soil; for every ounce measure of which two grains of carbonate of lime may be estimated.

L, Represents the stand for the lamp.

Stones.

Artificial STONE. See STUCCO.

Elastic STONE. Some marbles possess the property of elasticity, and hence come under the denomination of elastic stones. But the most remarkable stone of this nature is the elastic sandstone from Brazils. It is a micaceous sandstone in laminæ not exceeding half an inch in thickness. Some siliceous stones also have the same property, or acquire it by being exposed to a certain degree of heat.

Philosopher's STONE. See PHILOSOPHER'S *Stone.*

Precious STONES. See GEM.

Rocking STONE, or *Logan*, a stone of a prodigious size, so exactly poised, that it would rock or shake with the smallest force. Of these stones the ancients give us some account. Pliny says, that at Harpasa, a town of Asia, there was a rock of such a wonderful nature, that if touched with the finger it would shake, but could not be moved from its place with the whole force of the body*. Ptolemy Hephestion mentions † a gygonian stone near the ocean, which was agitated when struck by the stalk of an asphodel, but could not be removed by a great exertion of force. The word *gygonius* seems to be Celtic; for *gwingog* signifies *motitans*, the rocking-stone.

* Lib. ii. c. 69.

† Lib. iii. c. 3.

Many rocking stones are to be found in different parts of this island; some natural, others artificial, or placed in their position by human art. In the parish of St Leven, Cornwall, there is a promontory called *Castle Treryn*. On the western side of the middle group, near the top, lies a very large stone, so evenly poised that any hand may move it from one side to another; yet it is so fixed on its base, that no lever nor any mechanical force can remove it from its present situation. It is called the *Logan-stone*, and is at such a height from the ground that no person can believe that it was raised to its present position by art. But there are other rocking stones, which are so shaped and so situated, that there can be no doubt but they were erected by human strength. Of this kind Borlase thinks the great *Quoit* or *Karn-lehau*, in the parish of Tywidnek, to be. It is 39 feet in circumference, and four feet thick at a medium, and stands on a single pedestal. There is also a remarkable stone of the same kind in the island of St Agnes in Scilly. The under rock is 10 feet six inches high, 47 feet round the middle, and touches the ground with no more than half its base. The upper rock rests on one point only, and is so nicely balanced, that two or three men with a pole can move it. It is eight feet six inches high, and 47 in circumference. On the top there is a bason hollowed out, three feet eleven inches in diameter at a medium, but wider at the brim, and three feet deep. From the globular shape of this upper stone, it is highly probable that it was rounded by human art, and perhaps even placed on its pedestal by human strength. In Sithney parish, near Helston, in Cornwall, stood the famous logan, or rocking stone, commonly called *Men Amber*, q. d. *Men an Bar*, or the *top-stone*. It was eleven feet by six, and four high, and so nicely poised on another stone that a little child could move it, and all travellers who came this way desired to see it. But Shrubsall, Cromwell's governor of Pendennis, with much ado caused it to be undermined, to the great grief of the country. There are some marks of the tool on it, and, by its quadrangular shape, it was probably dedicated to Mercury.

Borlase, chap. iv. p. 181.

That the rocking stones are monuments erected by the Druids cannot be doubted; but tradition has not informed us for what purpose they were intended. Mr Toland thinks that the Druids made the people believe that they alone could move them, and that by a miracle; and that by this pretended miracle they condemned or acquitted the accused, and brought criminals to confess what could not otherwise be extorted from them. How far this conjecture is right we shall leave to those who are deeply versed in the knowledge of antiquities to determine.

Sonorous STONE, a kind of stone remarkable for emitting an agreeable sound when struck, and much used in China for making musical instruments which they call *king*.

The various kinds of sonorous stones known in China differ considerably from one another in beauty, and in the strength and duration of their tone; and what is very surprising, is that this difference cannot be discovered either by the different degrees of their hardness, weight, or fineness of grain, or by any other qualities which might be supposed to determine it. Some stones are found remarkably hard, which are very sonorous; and others exceedingly soft, which have an excellent tone; some extremely heavy emit a very sweet sound; and there are others as light as pumice stone which have also an agreeable sound.

The chemists and naturalists of Europe have never yet attempted to discover, whether some of our stones may not have the same properties as the sonorous stones of the extremities of Asia. It however appears, that the Romans were formerly acquainted with a sonorous stone of the class of *hiang-che*. Pliny (says the Abbé du Bos, in his Reflections on Poetry and Painting, when speaking of curious stones) observes that the stone called *chalcophonas*, or *brazen sound*, is black; and that, according to the etymology of its name, it sends forth a sound much resembling that of brass when it is struck. The passage of Pliny is as follows: *Chalcophonas nigra est; sed elisa æris tinnitum reddit.*

Some sonorous stones were at length sent into France, and

Stone, Stonehenge.

and the late Duke de Chaulnes examined them with particular attention. The following are ſome of his obſervations: "The Academy of Sciences, Mr Romé de Liſle, and ſeveral other learned mineralogiſts, when aſked if they were acquainted with the black ſtone of which the Chineſe king was made, for anſwer cited the paſſage of Pliny mentioned by Boethius de Bott, Linnæus, and in the Dictionary of Bomare, and added what Mr Anderſon ſays in his Natural Hiſtory of Iceland reſpecting a bluiſh kind of ſtone which is very ſonorous. As the black ſtone of the Chineſe becomes of a bluiſh colour when filed, it is probably of the ſame ſpecies. None of the reſt who were conſulted had ever ſeen it. The Chineſe ſtone has a great reſemblance at firſt ſight to black marble, and like it is calcareous; but marble generally is not ſonorous. It alſo externally reſembles touchſtone, which is a kind of baſaltes, and the baſaltes found near volcanoes; but theſe two ſtones are vitrifications."

The duke next endeavoured to procure ſome information from the ſtone-cutters. They all replied, that blue-coloured marble was very ſonorous, and that they had ſeen large blocks of it which emitted a very ſtrong ſound; but the duke having ordered a king to be conſtructed of this kind of ſtone, it was found that it did not poſſeſs that property. By trying the black marble of Flanders, a piece was at length found which emitted an agreeable ſound: it was cut into a king, which is almoſt as ſonorous as thoſe of China. All theſe obſervations give us reaſon to believe that the ſtones of which the king are formed are nothing elſe but a black kind of marble, the conſtituent parts of which are the ſame as thoſe of the marble of Europe, but that ſome difference in their organization renders them more or leſs ſonorous.

Swine-STONE (lapis ſuillus), or *fetid ſtone*, ſo called from its exceſſively fetid ſmell, is a calcareous ſtone impregnated with petroleum. See MINERALOGY *Index*.

STONE-Marrow, a variety of clay ſo called from its having the appearance of marrow.

STONE-Ware, a ſpecies of pottery ſo called from its hardneſs. See *DELFT-Ware* and PORCELAIN.

STONE in the Bladder. See MEDICINE, N° 400, and SURGERY *Index*.

STONE, in merchandize, denotes a certain weight for weighing commodities. A ſtone of beef at London is the quantity of eight pounds: in Herefordſhire 12 pounds: in the North 16 pounds. A ſtone of glaſs is five pounds; of wax eight pounds. A ſtone of wool (according to the ſtatute of 11 Hen. VII.) is to weigh 14 pounds; yet in ſome places it is more, in others leſs; as in Glouceſterſhire 15 pounds; in Herefordſhire 12 pounds. Among horſe-courſers a ſtone is the weight of 14 pounds.

The reaſon of the name is evident. Weights at firſt were generally made of ſtone. See Deut. xxv. 13. where the word אבן, tranſlated *weight*, properly ſignifies a *ſtone*.

STONE-Chatter. See MOTACILLA, ORNITHOLOGY *Index*.

STONEHENGE, a celebrated monument of antiquity, ſtands in the middle of a flat area near the ſummit of a hill ſix miles diſtant from Saliſbury. It is incloſed by a circular double bank and ditch near 30 feet broad, after croſſing which we aſcend 30 yards before we reach the work. The whole fabric conſiſted of two circles and two ovals. The outer circle is about 108 feet diameter, conſiſting when entire of 60 ſtones, 30 uprights and 30 impoſts, of which remain only 24 uprights, 17 ſtanding and 7 down, 3½ feet aſunder, and 8 impoſts. Eleven uprights have their 5 impoſts on them by the grand entrance. Theſe ſtones are from 13 to 20 feet high. The leſſer circle is ſomewhat more than 8 feet from the inſide of the outer one, and conſiſted of 40 leſſer ſtones (the higheſt 6 feet), of which only 19 remain, and only 11 ſtanding: the walk between theſe two circles is 300 feet in circumference. The Adytum or Cell is an oval formed of 10 ſtones (from 16 to 22 feet high), in pairs, with impoſts, which Dr Stukeley calls *trilithons*, and above 30 feet high, riſing in height as they go round, and each pair ſeparate. and not connected as the outer pair; the higheſt 8 feet. Within theſe are 19 more ſmaller ſingle ſtones, of which only 6 are ſtanding. At the upper end of the Adytum is the altar, a large ſlab of blue coarſe marble, 20 inches thick, 16 feet long, and 4 broad; preſſed down by the weight of the vaſt ſtones that have fallen upon it. The whole number of ſtones, uprights, impoſts, and altar, is exactly 140. The ſtones are far from being artificial, but were moſt probably brought from thoſe called the *Grey Weathers* on Marlborough Downs, 15 or 16 miles off; and if tried with a tool they appear of the ſame hardneſs, grain, and colour, generally reddiſh. The heads of oxen, deer, and other beaſts, have been found on digging in and about Stonehenge; and human bones in the circumjacent barrows. There are three entrances from the plain to this ſtructure, the moſt conſiderable of which is from the north-eaſt, and at each of them were raiſed on the outſide of the trench two huge ſtones with two ſmaller within parallel to them.

Stonehenge. Gough's edition of Camden's Britannia, vol. i. p. 107.

It has been long a diſpute among the learned, by what nation, and for what purpoſe, theſe enormous ſtones were collected and arranged. The firſt account of this ſtructure we meet with is in Geoffroy of Monmouth, who, in the reign of King Stephen, wrote the hiſtory of the Britons in Latin. He tells us, that it was erected by the counſel of Merlin the Britiſh enchanter, at the command of Aurelius Ambroſius the laſt Britiſh king, in memory of 460 Britons who were murdered by Hengiſt the Saxon. The next account is that of Polydore Virgil, who ſays that the Britons erected this as a ſepulchral monument of Aurelius Ambroſius. Others ſuppoſe it to have been a ſepulchral monument of Boadicea the famous Britiſh queen. Inigo Jones is of opinion, that it was a Roman temple; from a ſtone 16 feet long, and four broad, placed in an exact poſition to the eaſtward altar-faſhion. Mr Charlton attributed it to the Danes, who were two years maſters of Wiltſhire. A tin tablet, on which were ſome unknown characters, ſuppoſed to be Punic, was digged up near it in the reign of Henry VIII. but is loſt; probably that might have given ſome information reſpecting its founders. Its common name, *Stonehenge*, is Saxon, and ſignifies a "ſtone gallows," to which thoſe ſtones, having tranſverſe impoſts, bear ſome reſemblance. It is alſo called in Welch *choir gour*, or "the giants dance."

Mr Groſe thinks that Dr Stukeley has completely proved this ſtructure to have been a Britiſh temple in which the Druids officiated. He ſuppoſes it to have been the metropolitan temple of Great Britain, and tranſlates

translates the words *choir gour* "the great choir or temple." The learned Mr Bryant is of opinion that it was erected by a colony of Cuthites probably before the time of the Druids; because it was usual with them to place one vast stone upon another for a religious memorial; and these they often placed so equably, that even a breath of wind would sometimes make them vibrate. Of such stones one remains at this day in the pile of Stonehenge. The ancients distinguished stones erected with a religious view, by the name of *amber;* by which was signified any thing solar and divine. The Grecians called them πετραι αμβροσιαι, *petræ ambrosiæ*. Stonehenge, according to Mr Bryant, is composed of these amber stones: hence the next town is denominated *Ambresbury;* not from a Roman Ambrosius, for no such person ever existed, but from the *ambrosiæ petræ*, in whose vicinity it stood. Some of these were rocking stones; and there was a wonderful monument of this sort near Penzance in Cornwall, which still retains the name of *main-amber*, or the sacred stones. Such a one is mentioned by Apollonius Rhodius, supposed to have been raised in the time of the Argonautæ, in the island Tenos, as the monument of the two-winged sons of Boreas, slain by Hercules; and there are others in China and other countries.

Grose's Antiquities, vol iv. p. 40.

STOOK, a term used in many parts of the kingdom for a shock of corn containing 12 sheaves.

STOOL, in *Medicine*, an evacuation or discharge of the fæces by the anus.

STOOL, in *Mining*, is used when the miners leave off digging deeper, and work in the ends forward. The end before them is called the *stool.*

STOOL, in *Ship building*, the name of the supporters of the poop and top lanterns.

STOOPING, in *Falconry*, is when a hawk, being upon her wings at the height of her pitch, bends down violently to take the fowl.

STOPPERS, in a ship, certain short pieces of rope, which are usually knotted at one or both ends, according to the purpose for which they are designed. They are either used to suspend any heavy body, or to retain a cable, shroud, &c. in a fixed position. Thus, the anchors, when first hoisted up from the ground, are hung to the cat head by a stopper attached to the latter, which passing through the anchor-ring, is afterwards fastened to the timber-head; and the same rope serves to fasten it on the bow at sea; or to suspend it by the ring which is to be sunk from the ship to the bottom. The stoppers of the cable have a large knot and a laniard at one end, and are fastened to a ring-bolt in the deck by the other. They are attached to the cable by the laniard, which is fastened securely round both by several turns passed behind the knot, or about the neck of the stopper; by which means the cable is restrained from running out of the ship when she rides at anchor.

The stoppers of the shroud have a knot and a laniard at each end. They are only used when the shrouds are cut asunder in battle, or disabled by tempestuous weather: at which time they are lashed, in the same manner as those of the cables, to the separated parts of the shroud, which are thereby reunited, so as to be fit for immediate service. This, however, is only a temporary expedient.

STOPS. See PUNCTUATION; and SCRIPTURE, N° 136.

STORAX. See STYRAX, MATERIA MEDICA *Index*.

STORK. See ARDEA, ORNITHOLOGY *Index*.

STOVE for heating apartments, greenhouses, hothouses, fruit-walls, &c.

When treating of the mechanical properties of air, we explained in sufficient detail the manner in which the expansion produced in a mass of air by heat produces that motion up our chimneys which is called the draught of the chimney; and, in the article SMOKE, we considered the circumstances which tend to check, to promote, or to direct this current, so as to free us from the smoke and vitiated air which necessarily accompanies the consumption of the fuel. In PNEUMATICS we also attended to the manner in which our fires immediately operate in warming our apartments. At present, when about to describe a method of warming intrinsically different, we must pay some more attention to the distinguishing circumstance. Without pretending to explain the physical connection of heat and light, it may suffice to observe, that heat, as well as light, is communicated to distant bodies in an instant by radiation. A person passing hastily by the door of a glass-house feels the glow of heat in the very moment he sees the dazzling light of the furnace mouth, and it is interrupted by merely screening his face with his hand. In this way is an apartment partly warmed by an open fire; and we avoid the oppressive heat by sitting where the fire is not seen, or by interposing a screen. We are apt to connect this so strongly in the imagination with the light emitted by the fire, that we attribute the heat to the immediate action of the light. But this opinion is shown to be gratuitous by a curious experiment made before the Royal Society by Dr Hooke, and afterwards, with more care and accurate examination, by Mr Scheele. They found, that by bringing a plate of the most transparent glass briskly between the fire and one's face, the heat is immediately intercepted without any sensible diminution of the light. Scheele, by a very pretty investigation, discovered that the glass made the separation, and did it both in refraction and reflection; for he found, that when the light of the same fire was collected into a focus by means of a polished metal concave speculum, a thermometer placed there was *instantly* affected. But if we employ a glass speculum foiled in the usual manner with quicksilver, of the same diameter and focal distance, and of equally brilliant reflection, there is hardly any sensible heat produced in the focus, and the thermometer must remain there for a very long while before it is sensibly affected. When we repeated this curious experiment, we found, that after the glass has remained a long while in this position, whether transmitting or reflecting the light, it loses in a great measure its power of intercepting the heat. By varying this observation in many of its circumstances, we think ourselves entitled to conclude, that the glass absorbs the heat which it intercepts, and is very quickly heated by the absorption. While it rises in its own temperature, it intercepts the heat powerfully; but when it is, as it were, saturated, attracting no more than what it immediately imparts to the air in corporeal contact with it, the heat passes freely through along with the light. If the

the glaſs be held ſo near the fire that the ſurrounding air is very much heated, no ſenſible interruption of heat is perceived after the glaſs is thus ſaturated. We found the cheek more quickly ſenſible than the thermometer of this inſtantaneous radiation of the heat which accompanies the light, or is ſeparated from it in this experiment. It is a very inſtructive experiment in the phyſiology of heat.

We cannot ſay how far this radiation of heat may extend, nor whether the accompanyment of light is abſolutely neceſſary. The mathematician proceeds on the ſuppoſition that it extends as far as the radiation of light, and that, being alſo rectilineal, the denſity of the heat is proportional to that of the light. But theſe notions are ſomewhat gratuitous; and there are appearances which render them doubtful. When with a lens of an inch in diameter we form a focus on a piece of black unpoliſhed marble of an inch diameter, the mathematician muſt allow that no more rays fall on the marble than if the lens were away: therefore the marble ſhould be equally warmed in either caſe. But it is by no means ſo, as we have repeatedly found by expoſing it during equal times, and then dropping it into water. The water which is heated by the marble on which the focus has been formed will be found to have acquired from it much more heat than from the other. The tops of lofty mountains which are never ſhaded by clouds, but enjoy perpetual ſunſhine and ſerenity, inſtead of being warmer than the valleys below, are covered with never-melting ſnow; and we have ſome grounds to ſuſpect that the genial influence of the ſun requires the co-operation of the atmoſphere, and to doubt whether there is any warmth at the moon, on which no atmoſphere like ours can be obſerved. Perhaps the heat which cheers us, and fertilizes our earth, is chemically ſeparated from our atmoſphere by its elective attraction for the light of the ſun. Our ſucceſſors in the ſtudy of meteorology need not fear that the ſubject of their reſearch will be ſoon deprived of ſcientific allurements. We know but little of it after all the progreſs we have made during this laſt century, and it ſtill preſents an ample field of diſcuſſion.

We ſaid that the accompaniment of light is not demonſtrably neceſſary. We are certain that heat may be imparted without any ſenſible light, in a manner which we can hardly ſuppoſe any thing but radiation. If a piece of very hot iron be placed a little without the principal focus of a metallic concave ſpeculum, and a very ſenſible air-thermometer be placed in its conjugate focus, it will inſtantly ſhow an elevation of temperature, although the iron is quite imperceptible to an eye which has even been a long while in the dark. No ſuch riſe of temperature is obſerved if the thermometer be placed a little to one ſide of the focus of the ſpeculum; therefore the phenomenon is preciſely ſimilar to the radiation of light. We are obliged therefore to acknowledge that the heat is radiated in this experiment in the ſame way that light is in the common optical experiments.

Although this is the moſt uſual way that we in this country employ fuel for warming our apartments, it is by no means the only way in which the heat diffuſed from this fuel may be imparted to diſtant bodies. It is not even the moſt effectual method; it is diffuſed alſo by immediate communication to bodies in contact. The air in immediate contact with the burning fuel is heated, and imparts ſome of its heat to the air lying beyond it, and this is partly ſhared with the air which is ſtill farther off; and this diffuſion, by communication *in contactu*, goes on till the remote air contiguous to the walls, the floor, the ceiling, the furniture, the company, all get a ſhare of it in proportion to their attractions and their capacities. And as the air is thus continually ſupplied, and continually gives out heat, the walls, &c. become gradually warmer, and the room becomes comfortable and pleaſant. But we apprehend that no great proportion of the heat actually acquired by the room is communicated in this way. This diffuſion by contact is but ſlow, eſpecially in air which is very dry; ſo ſlow indeed, that the air in the immediate neighbourhood of the fuel is hurried up the chimney before it has time to impart any of the heat received in contact. We know that the time employed in diffuſing itſelf in this way through ſtagnant air to any moderate diſtance is very conſiderable. We imagine therefore that the heat communicated to our rooms by an open fire is chiefly by radiation, but in a way ſomething different from what we mentioned before. We imagine, that as the piece of glaſs in Dr Hooke's experiment abſorbs the heat, ſo the whole maſs of air which fills the room intercepts the radiated heat in every part of the room where the fire is ſeen, and is as it were ſaturated with it throughout, and ready to impart it to every body immerſed in it. We cannot otherwiſe account for the *equability* of the heat in the different parts of the room. Mere radiation on the ſolid bodies would warm them in the inverſe duplicate ratio of their diſtances from the fire; and diffuſion by contact, if compatible with the rapid current up the chimney, would heat the room ſtill more unequably. Recollect how ſlowly, and with what rapid diminution of intenſity, the colour of blue vitriol is communicated to water even to a very ſmall diſtance. But becauſe all parts of the air of the room abſorb radiated heat, what is ſaturated at a higher temperature, being nearer to the fire, riſes to the ceiling, ſpreads outwards along the ceiling, and has its place ſupplied by the air, which is thus puſhed towards the fire from the places which are not directly illuminated.

Far different is the method of warming the room by a ſtove. Here the radiation, if any, is very feeble or ſcanty; and if a paſſage were allowed up the chimney for the warmed air, it would be quickly carried off. This is well known to the Engliſh who reſide in the cold climates of St Peterſburgh, Archangel, &c. They love the exhilerating flutter of an open fire, and often have one in their parlour; but this, ſo far from warming the room during the extreme cold weather, obliges them to heat their ſtoves more frequently, and even abſtracts the heat from a whole ſuite of apartments. But all paſſage this way is ſhut up when we warm a room by ſtoves. The air immediately contiguous to the ſtove is heated by contact, and this heat is gradually, though ſlowly, diffuſed through the whole room. The diffuſion would however be very ſlow indeed, were it not for the great expanſibility of air by heat. But the air ſurrounding the ſtove quickly expands and riſes to the ceiling, while the neighbouring air ſlides in to ſupply the place, nay is even puſhed in by the air which goes outwards aloft. Thus the whole air is ſoon mixed, and the room acquires almoſt an equal temperature throughout.

Stove.

The warming by ſtoves muſt therefore be managed upon very different principles from thoſe adopted in the employment of open fires. The general principle is, 1ſt, To employ the fuel in the moſt effectual manner for heating the external part of the ſtove, which is immediately efficient in warming the contiguous air; and, 2d, To keep in the room the air already warmed, at leaſt as much as is conſiſtent with wholeſomeneſs and cleanlineſs.

The firſt purpoſe is accompliſhed by conducting the flue of the furnace round its external parts, or, in ſhort, by making every part of the flue external. Of all forms, that of a long pipe, returned backwards and forwards, up and down (provided only that the place of its laſt diſcharge be conſiderably higher than its entry from the fire-place), would be the moſt effectual. We have ſeen a very ſmall ſtove conſtructed in this way, the whole being incloſed in a handſome caſe of poliſhed iron plate, pierced and cut into elegant foliage like the cock of a watch, ſo that the odd looking pipes were completely concealed. Though only three feet long, one foot thick, and ſix feet high, it warmed a very lofty room of 24 feet by 18, and conſumed leſs than half the fuel of a ſtove of the more uſual make, which did not ſo fully warm a ſmaller chamber.

It would occupy a volume to deſcribe the immenſe variety of ſtoves which ingenuity or architectonic taſte has conſtructed. We ſhall content ourſelves with giving a ſpecimen of the two chief claſſes into which they may be diſtinguiſhed.

The air of a room may be equally warmed, either by applying it to the ſurface of a ſmall ſtove made very hot, or to the ſurface of a much larger ſtove more moderately heated. The firſt kind is chiefly uſed in Holland, Flanders, and the milder climates of Germany and Poland. The laſt are univerſally uſed in the frozen climates of Ruſſia and Sweden. The firſt are generally made of caſt-iron, and the laſt of brick-work covered with glazed tiles or ſtucco.

Plate DX. Fig. 1.

Fig. 1. repreſents a ſmall German ſtove fully ſufficient for warming a room of 24 feet by 18. The baſe is about three feet broad and 14 inches deep, that is, from back to front, and ſix or ſeven feet high. The decoration is in the faſhion of that country; but the operative ſtructure of it will admit of any ſtyle of ornament. A, is the fire-place, and the wood or charred coal is laid on the bottom, which has no bars. Bars would admit the air too freely among the fuel, and would both conſume it too faſt and raiſe too great a heat. That no heat may be uſeleſsly expended, the ſole of the fire-place and the whole bottom of the ſtove is raiſed an inch or two above the floor of the room, and the air is therefore warmed by it in ſucceſſion, and riſes upwards. For the ſame reaſon the back of the ſtove is not in contact with the wall of the room, or of the niche in which it is placed. The fire-place is ſhut up by a door which fits cloſely to its caſe, and has a ſmall wicket at the bottom, whoſe aperture is regulated by a ſliding plate, ſo as to admit no more air than what ſuffices for ſlowly conſuming the fuel. The flame and heated air riſe to the top of the fire-place three or four inches above the arch or mantle-piece, and get out laterally by two narrow paſſages B, B, immediately below the top-plate of the baſe. The current bends downward on each ſide, paſſes at C, C, under the partition plates which divide the two ſide chambers, and then riſes upwards through the outer diviſion of each, and paſſes through narrow ſlits D, D, in the top plate, and from thence along the two hollow piers E, E. The two lateral currents unite at the top of the arch, and go through the ſingle paſſage F into the larger hollow behind the eſcutcheon G. From this place it either goes ſtraight upwards into the vent in the wall by a pipe on the top of the ſtove, or it goes into the wall behind by a pipe inſerted in the back of the ſtove. The propriety of this conſtruction is very obvious. The current of hot air is applied to exterior parts of the ſtove everywhere except in the two ſide chambers of the baſe, where the partition-plates form one ſide of the canal. Even this might be avoided by making each of theſe ſide-chambers a detached hollow pillar. But this would greatly increaſe the trouble of conſtruction and joining together, and is by no means neceſſary. The arch H has a graceful appearance, and affords a very warm ſituation for any thing that requires it, ſuch as a drink in a ſick perſon's bed-chamber, &c. Perſons of a certain claſs uſe this place for keeping a diſh warm; nay, the lower part of the arch is frequently occupied by an incloſed chamber, where the heat riſes high enough even for dreſſing victuals, as will be eaſily imagined when we reflect that the ſole of it is the roof of the fire-place.

The ſtove now deſcribed is ſupplied with fuel and with air by the front door opening into the room. That there may be room for fuel, this middle part projects a few inches before the two ſide-chambers. Theſe laſt, with the whole upper part of the ſtove, are not more than ten inches deep. The paſſages, therefore, from the fire-place are towards the back of it; ſo that if we have a mind to ſee the fire (which is always cheerful), the door may be thrown open, and there is no danger of the ſmoke coming out after the current has once warmed the upper part of the ſtove. When the ſtove is of ſuch dimenſions that the baſe is about two feet and a half or three feet high, the fire-place may be furniſhed with a ſmall grate in the Britiſh ſtyle. If the door is ſo hung that it can not only be thrown back, but lifted off its hinges, we have a ſtove grate of the completeſt kind, fully adequate, in our mild climate, to warm a handſome apartment, even with an open fire; and when we hang on the door, and ſhut up the fire-place, a ſtove of the dimenſions already given is almoſt too much for a large drawing room.

We have frequently remarked, that one ſide of theſe ſtoves grows much warmer than the other, and that it was difficult to prevent or remedy this; and we imagine that this is an unavoidable defect in all ſtoves with a double flue. It is ſcarcely poſſible to make the fire ſo equable in the fire-place, that one ſide ſhall not be a little warmer than the other, and a briſker current will then be produced in it. This muſt increaſe the conſumption of the fuel on this ſide, which will increaſe the current, will heat this ſide ſtill more, and thus go on continually till the fuel on this ſide is expended; after which the other ſide will obtain and increaſe the ſuperiority. The flue is made double, that the fire-place may occupy the middle of the front; and it will be difficult to gain this point of ſymmetry with one flue. The inconvenience may, however, be corrected by damping valves placed in ſome part of the upright funnels E, E.

In

In the colder winters on the continent, it is thought neceffary to increafe the effect by making the fire-place open to the back of the ftove. Its mouth or door communicates with or is joined to an opening of the fame dimenfions formed in the wall, and the door is on the other fide in an antichamber or lobby. In Weftphalia, and other places of Germany, the apartments are difpofed round a fpacious lobby, into which all their fire-places open, and are there fupplied with fuel. By this conftruction it is plain that the air of the room, already warmed by the ftove, is not carried off, and the room is more heated. But this method is very unfavourable to cheerfulnefs and health. The fame air, confined, and repeatedly breathed and compounded with all the volatile emanations of the room, quickly lofes that refrefhing quality that is fo defirable, and even fo neceffary for health. It is never renewed except by very partial admixtures when the room doors are thrown open, and becomes difagreeable to any perfon coming in from the open air; and in the houfes of the lefs opulent becomes really offenfive and naufeous.

Something of this is unavoidable in all rooms heated by ftoves. Even in our apartments in this ifland, perfons of delicate nerves are hurt by what they call the clofe air of a room; and it is long before the fmell of dinner is quite removed from a dining-room, notwithftanding the copious current up the chimney. This muft be incomparably more fenfible in a room heated by a ftove; and this inconvenience is peculiarly fenfible with refpect to the ftove which we are confidering at prefent, where we employ a fmall furface heated to a great degree.

Such ftoves are feldom made of any thing elfe than caft-iron. This (in thofe parts at leaft which are in immediate contact with the fuel) is in a ftate of continual calcination, and even throwing off fcales. This indeed is not feen, becaufe it is the bottom or fole of the fire-place which is fo heated: but the effect on the air of the room is the fame. The calcination of the iron is occafioned by the combination of pure vital air with the iron. This is abftracted from the general mafs of atmofpheric air in the room, of which it ufually conftitutes about two-fifths. By this abftraction the remainder becomes lefs fit for fupporting animal life or flame, and may even become highly deleterious. In every degree the remainder becomes lefs refrefhing, and grows dull and oppreffive. This is always accompanied by a peculiar fmell, which, though not difgufting, is unpleafant. It refembles the fmell of burnt feathers, or more exactly the fmell we feel if we rub violently for fome time the palms of our hands together when perfectly dry.

For fimilar reafons thefe iron ftoves occafion a fickly fmell, by burning every particle of duft which falls on the hot parts; and if they be wiped with a woollen cloth, or any cloth not perfectly free from every kind of greafy or oily matter, a fmell is produced for a day or days afterwards; fo that without the moft fcrupulous attention we fuffer by our very cleanlinefs.

For fuch reafons we think that the ftoves of brick-work covered with ftucco or with glazed tiles are vaftly preferable. Thefe are much ufed in the genteeler houfes in Flanders and Holland, where they are made in the moft elegant forms, and decorated with beautiful fculpture or enamel; but it is plain that they cannot be fo effectual, nor equally warm a room with the fame expence of fuel. Earthen ware, efpecially when covered with porous ftucco, is far inferior to metal in its power of conducting heat. If built of bricks, they muft be vaftly more bulky when the fire-place and flues are of the fame dimenfions. The moft perfect way of conftructing them would certainly be to make them of pottery, in parts exactly fitted to each other, and joined by a proper cement. This mode of conftructing would admit of every elegance of form or richnefs of ornament, and would not be fo bulky as thofe which are built of bricks. The great difficulty is to prevent their cracking by the heat. Different parts of the ftove being of very different heats, they expand unequally, and there is no cement which can withftand this, efpecially when we recollect that the fame heat which expands the baked earth caufes the clay or cement, with which the parts of the ftove are put together or covered, to contract. Accordingly thofe earthen ware ftoves feldom ftand a winter or two without cracking in fome place or other, even when ftrengthened by iron hoops and cramps judicioufly difpofed within them. Even hooping them them externally, which would be very unfightly, will not prevent this; for nothing can refift the expanfion and contraction by heat and cold. When a crack happens in a ftove, it is not only unfightly, but highly dangerous; becaufe it may be fo fituated, that it will difcharge into the room the air vitiated by the fire.

For thefe and other reafons, we can fcarcely hope to make ftoves of brick-work or pottery which fhall bear the neceffary heat without cracking; and their ufe muft therefore be confined to cafes where very moderate heat is fufficient. We need not defcribe their conftruction. It is evident that it fhould be more fimple than that of iron ftoves; and we imagine that in the very few cafes in which they are likely to be employed in this country, a fingle fire-place and an arch over it, divided, if we pleafe, by a partition or two of thin tile to lengthen the flue, will be quite enough. If the ftove is made in whole or in part of potters ware, a bafe for the fire-place, with an urn, column, obelifk, or pyramid above it, for increafing the furface, will alfo be fufficient. The failure commonly happens at the joinings, where the different pieces of a different heat, and perhaps of a different baking, are apt to expand unequally, and by working on each other one of them muft give way. Therefore, inftead of making the joints clofe and ufing any cement, the upper piece fhould ftand in a groove formed in the undermoft, having a little powdered chalk or clay fprinkled over it, which will effectually prevent the paffage of any air; and room being thus given for the unequal expanfion, the joint remains entire. This may be confidered as a general direction for all furnace-work, where it is in vain to attempt to hinder the mutual working of the parts.

We have feen ftoves in fmall apartments at St Peterfburg, which were made internally of potters ware, in a great variety of forms, and then covered with a thick coat of ftucco, finifhed externally with the utmoft elegance of ornament, and we were informed that they were very rarely fubject to crack. They did not give much heat, on account of the very low conducting power of the porous ftucco; but we imagine that they would be abundantly warm for a moderate room in this country.

When

When fitted up in thefe fituations, and with thefe precautions, the brick or pottery ftoves are incomparably more fweet and pleafant than the iron ones.

But in the intenfe colds of Ruffia and Sweden, or even for very large rooms in this kingdom, ftoves of thefe fmall dimenfions are not fufficiently powerful, and we muft follow the practice of thofe countries where they are made of great fize, and very moderately heated. It is needlefs to defcribe their external form, which may be varied at pleafure. Their internal ftructure is the fame in all, and is diftinctly defcribed in PNEUMATICS, N° 364. We fhall only enlarge a little on the peculiarities connected with the general principle of their conftruction.

The ftove is intended as a fort of magazine, in which a great quantity of heat may be quickly accumulated, to be afterwards flowly communicated to the air of the room. The ftove is therefore built extremely maffive; and it is found that they are more powerful when coated with clay as wet as can be made to hang together. We imagine the reafon of this to be, that very wet clay, and more particularly ftucco, muft be exceedingly porous when dry, and therefore a very flow conductor of heat. Inftead of fticking on the glazed tiles with no more clay or ftucco than is fufficient to attach them, each tile has at its back a fort of box baked in one piece about two or three inches deep. It is reprefented in

Fig. 2. fig. 2. This is filled with mortar, and then ftuck on the brick-work of the ftove, which has a great number of iron pins or hooks driven into the joints, which may fink into this clay and keep it firmly attached when dry. This coating, with the maffive brick-work, forms a great mafs of matter to be heated by the fuel. The loweft chamber, which is the fire-place, is fomewhat wider, and confiderably thicker than the ftories above, which are merely flues. When the fire-place is finifhed and about to be arched over, a flat iron bar of fmall thicknefs is laid along the top of the fide-wall on both fides, a fet of finifhing bricks being moulded on purpofe with a notch to receive the iron bar. Crofs bars are laid over thefe, one at each end and one or two between, having a bit turned down at the ends, which takes hold of the longitudinal bars, and keeps them from being thruft outwards either by the preffure of the arch or by the fwelling in confequence of the heat. In

Fig. 3. fig. 3. A is the crofs fection of one of the long bars, and BC is part of one of the crofs bars, and CD is the clench which confines the bar A. This precaution is chiefly neceffary, becaufe the contraction of the ftove upwards obliges the walls of the other ftories to bear a little on the arch of the fire-place. The building above is kept together in like manner by other courfes of iron bars at every fecond return of the flue. The top of the ftove is finifhed by a pretty thick covering of brick-work. The laft paffage for the air at H (fee PNEUMATICS, fig. 62.) has a ring lining its upper extremity, and projecting an inch or two above it. The flat round it is covered with fand. When we would ftop this paffage, a covered fhape like a bafon or cover for difhes at table is whelmed over it. The rim of this, refting on the fand, effectually prevents all air from coming through and getting up the vent. Accefs is had to this damper by a door which can be fhut tight enough to prevent the heated air of the room from wafting itfelf up the vent. When the room is too warm, it may be very rapidly cooled by opening this door. The warm air rufhes up with great rapidity, and is replaced by cool air from without.

The management of the ftove is as follows. About eight o'clock in the morning the *pietchnick*, or fervant who has the charge of the ftoves, takes off the cover, fhuts the damper-door, and opens the fire-place door. He then puts in a handful of wood fhavings or ftraw, and kindles it. This warms the ftove and vent, and begins a current of air through it. He then lays a few chips on the fole of the fire-place, immediately within the door; and behind this he arranges the billets of birchwood, with their ends inwards. Then he lays on more wood in the front, till he thinks there is enough. He fets fire to the chips, fhuts the door, and opens the fmall wicket at its bottom. The air blows the flame of the chips upon the billets behind them, and thus kindles them. They confume flowly, while the billets in front remain untouched by the fire. The fervant, having made his firft round of the rooms, returns to this ftove, and opens the door above to admit air into the vent. This is to fupply its draught, and thus to check the draught in the body of the ftove, which is generally too ftrong at this time, and would confume the fuel too faft. By this time the billets in the front are burning, firft at the bottom, and the reft in fucceffion as they fink down on the embers and come oppofite to the wicket. The room does not yet feel any effect from the fire, the heat of which has not yet reached its external furface; but in about half an hour this grows warm. The upper door is fhut again, that no heat may now be wafted. The pietchnick by and by fpreads the embers and afhes over the whole bottom of the fire-place with a rake, by which the bottom is greatly heated, and heats the air contiguous to it externally (for it ftands on little pillars) very powerfully. He takes care to bring up to the top of the afhes every bit of wood or coal that is not yet confumed, that all may be completely expended. He does this as brifkly as poffible, that the room may not lofe much warmed air by keeping open the fire-place door. At his laft vifit, when he obferves no more glowing embers, he fhuts the fire-place door and wicket, and puts the damper on the paffage above, and fhuts its door.—All this is over in about an hour and a half after kindling the fire. All current of air is now at an end within the ftove, and it is now a great mafs of brick-work, heated to a great degree within, but only about blood-warm externally. The heat gradually fpreads outwards, and the external furface of the ftove acquires its greateft heat about three o'clock in the afternoon; after which it gradually cools till next morning.

This heat feldom is fo great that one cannot bear to touch the ftove with his cheek, and to keep it there. In confequence of this it can burn none of the duft which unavoidably falls on the ftove, and we are never troubled with the fickening fmells that are unavoidable when we employ the fmall caft-iron ftoves much heated. The great expence of heat in a room arifes from the glafs windows. The pane is fo thin that the external air keeps it continually cold, and thus the windows are continually robbing the air of the room of its heat. This expence of heat is reduced to lefs than one-third by double cafements. The inner cafement is about as much colder than the room as the outer cafement is

 warmer

warmer than the air of the fields; and we have the singular advantage of having no ice formed on the glaffes. But to enfure this laft advantage, the feams of the inner cafement muft be pafted with paper, and thofe of the outer cafement muft be left unpafted. If we do the contrary, we fhall certainly have ice on the outer cafement; the reafon of which is eafily feen.

We have been thus particular in our defcription of the management, becaufe the reafons of fome particulars are not very obvious, and the practice would not readily occur to us in this country; fo that a perfon who, on the faith of our recommendation, fhould prefer one of thefe ftoves to the German ftove, whofe management is fimple and obvious, might be greatly difappointed. But by following this method, we are confident that the Ruffian ftove will be found much fuperior both in warmth and agreeable air. The fpreading out of the embers, and waiting till all is reduced to afhes before the doors are fhut, is alfo abfolutely neceffary, and a neglect of it would expofe us to imminent danger of fuffocation by fixed air; and this is the only inconvenience of the Ruffian ftove, from which the other ftove is free. The fixed air has no fmell; and the firft indication of its prefence is a flight giddinefs and laffitude, which difpofes us to fit down and to fleep. This would be fatal; and we muft immediately open the upper paffage and the fireplace door, fo as to produce a ftrong current to carry the vitiated air of the room up the chimney. Throwing up the fafhes, or at leaft opening all the doors, is proper on fuch an occafion.

If we burn pit-coal, either raw or charred, this precaution is ftill more neceffary; becaufe the cinder is not fo eafily or fo foon completely confumed. This fuel will require a little difference in the management from wood fuel, but which is eafily feen by any perfon of reflection. The fafe way would be to rake out all half-burnt coal before fhutting up the doors.

If we ufe raw pit-coal, great care is neceffary to prevent the accumulation of foot in the upper part of the ftove. It is an inacceffible place for the chimney-fweep; and if we attempt to burn it out, we run a great rifk of fplitting that part of the ftove which is the moft flightly conftructed. It is advifable therefore to burn it away every day, by giving a brifk draught with an open door for five minutes. With wood or coak there is no danger.

It will not be improper in this place to give fome inftructions for the conftruction of ftoves for warming feveral floors in a great manufactory, fuch as a cotton-mill, or a public library or mufeum.

In fuch fituations we think cleanlinefs, wholefomenefs, and fweetnefs of air, no lefs neceffary than in the drawing room of a man of opulence. We therefore recommend the brick-ftove in preference to the iron one; and though it would not be the beft or moft economical practice to heat it but once a-day, and we fhould rather prefer the German practice of conftant feeding, we ftill think it highly proper to limit the heat to a very moderate degree, and employ a large furface.

If the difpofition of the rooms allows us the conveniency of a thick party-wall, we would place the ftove in the middle of this wall, in an arch which pierces through the wall. Immediately above this arch we would carry up a very wide chimney through the whole height. This chimney muft have a paffage opening into each floor on both fides, which may be very accurately fhut up by a door. The ftove being fet up under the arch, it muft have a pipe communicating with its flue, and rifing up through this chimney. Could an earthen pipe be properly fupported, and fecured from fplitting by hoops, we fhould prefer it for the reafons already given. But as this is perhaps expecting too much, we muft admit the ufe of a caft iron pipe. This is the real chimney or flue of the ftove, and muft be of as great diameter as poffible, that it may act, by an extenfive furface, all the way up.

The ftove ftands under the arch in the wall; but the air that is warmed by its furface would efcape on both fides, and would be expended in that fingle floor. To prevent this, the ftove muft be inclofed in a cafe: this may be of brick-work, at the diftance of two or three inches from the ftove all round. It muft be well fhut in above, and at the foundation muft have a row of fmall holes to admit the air all around it. This air will then be warmed over the whole fpace between the ftove and the cafe, pafs up the chimney, and there receive additional heat from the flue-pipe which is in the middle. Great care muft be taken that the fire-place door have no communication with the fpace between the ftove and its cafe, but be inclofed in a mouth-piece which comes through the cafe, and opens into the feeding room. Thus all the air which goes up to the rooms will be pure and wholefome, provided we take care that every thing be kept clean and fweet about the air-holes below. Obferve that thofe air-holes which are near the furnace door muft be inclofed in a wooden trunk which takes in its air at fome diftance from this door; for fince the current between the ftove and cafe may be almoft as great as the current within the ftove (nay, when a puff of wind beats down the chimney, it may even exceed it), there is a rifk of fome vitiated air and fmoke being drawn into the cafe.

If the ftove cannot be placed in the arch of a party-wall, it may be fet adjoining to a fide or outer wall, and furnifhed with a cafe, a large chimney, and a flue-pipe, in the fame manner. But in this cafe a great deal of heat is wafted on this outer wall, and carried off by the external air. In this fituation we would recommend to line that part of the wall which is behind the ftove (at two or three inches diftance), and the whole of the chimney, with plafter on laths. Thefe fhould be nailed on battens properly faftened on the wall, leaving a fpace of an inch between the laths and the wall. The plafter fhould be of the moft fpungy kind, having in it a quantity of clay in powder inftead of the full proportion of fand. Horfe-dung, wafhed with water and ftrained through coarfe flannel, leaves a great portion of unaffimilated vegetable fibre, which will mix very intimately in the plafter, and make it a fubftance very unfit for conducting heat. There is no danger of catching fire by this lining. We have feen a moft tremendous fire rage for three hours, in contact with a partition of lath and plafter (on the plafter-fide however), without difcolouring the thin laths on the other fide. We once faw a cottage chimney on fire, and burn till the foot was confumed. This chimney was nothing but a pipe of a foot wide, made of laths, and plaftered on the infide and outfide; and it paffed through a thatched roof. We therefore recommend this in place of the brick-cafe for inclofing the ftove. It would fave heat; and as it might be be made in pieces on detached frames, which could be joined by iron ftraps and hinges, any part of the ftove could be laid open for repairs at pleafure.

We have no hefitation in faying that a ftove conftructed in this manner would be greatly fuperior in power to any we have feen, and would be free from many of their difgufting defects. We beg leave therefore to introduce here the defcription of one which was to have been erected in one of the churches of the city of Edinburgh.

Fig. 4.

Fig. 4. is a fketch of the plan of the church contained in the parallelogram AFED. P marks the place of the pulpit, and LMNO the front of the galleries. Thefe are carried back to the fide-walls AB and DC. But at the end oppofite to the pulpit they do not reach fo far, but leave a fpace BFEC about 12 feet wide. Below the back of the galleries, on each fide, there is a paffage ABGH, KICD, feparated from the feated part of the church by partitions which reach from the floor to the galleries, fo that the fpace HGIK is completely fhut in. The church is an ancient Gothic building, of a light and airy ftructure, having two rows of large windows above the arcades, and a fpacious window in the eaft end above the pulpit. The congregation complain of a cold air, which they feel pouring down upon their heads. This is more particularly felt by thofe fitting in the fronts of the galleries. We imagine that this arifes chiefly from the extenfive furface of the upper row of windows, and of the cold ftone-walls above, which robs the air of its heat as it glides up along the fides of the church. It becomes heavier by collapfing, and in this ftate defcends in the middle of the church.

The ftove S is placed againft the middle of the weft wall at the diftance of a few inches, and is completely inclofed in a cafe of lath and plafter. The vent, which is to carry off the fmoke and burnt air, is conveyed up or along the wall, and through the roof or fide-wall, but without any communication with the cafe. In like manner the fire-place door is open to the paffage, without communicating with the cafe; and care is taken that the holes which admit the air into the cafe are fo difpofed that they fhall run no rifk of drawing in any air from the fire-place door.

From the top of this cafe proceed two trunks Q, R, each of which is two feet broad and fix inches deep, coated within and without with the moft fpungy plafter that can be compofed. For this purpofe we fhould recommend a compofition of powdered charcoal and as much clay and quicklime as will give it a very flight cohefion. We know that a piece of this may be held in the hand, without inconvenience, within an inch of where it is of a glowing red heat.—Thefe trunks open into another trunk XVTYZ, which ranges along the partition immediately under the galleries, and may be formed externally into a corniche, a little maffive indeed, but not unfightly in a building of this ftyle. This trunk is coated in the fame manner. It has feveral openings *a*, *a*, &c. which have fliders that can be drawn afide by means of handles acceffible from the outer paffage.—At the extremities X and Z of this trunk are two perpendicular trunks which come up through the galleries, and are continued to a confiderable height. At their junction with the horizontal trunk are two doors large enough to admit a lamp. Each perpendicular trunk has alfo a valve by which it can be completely ftopped.

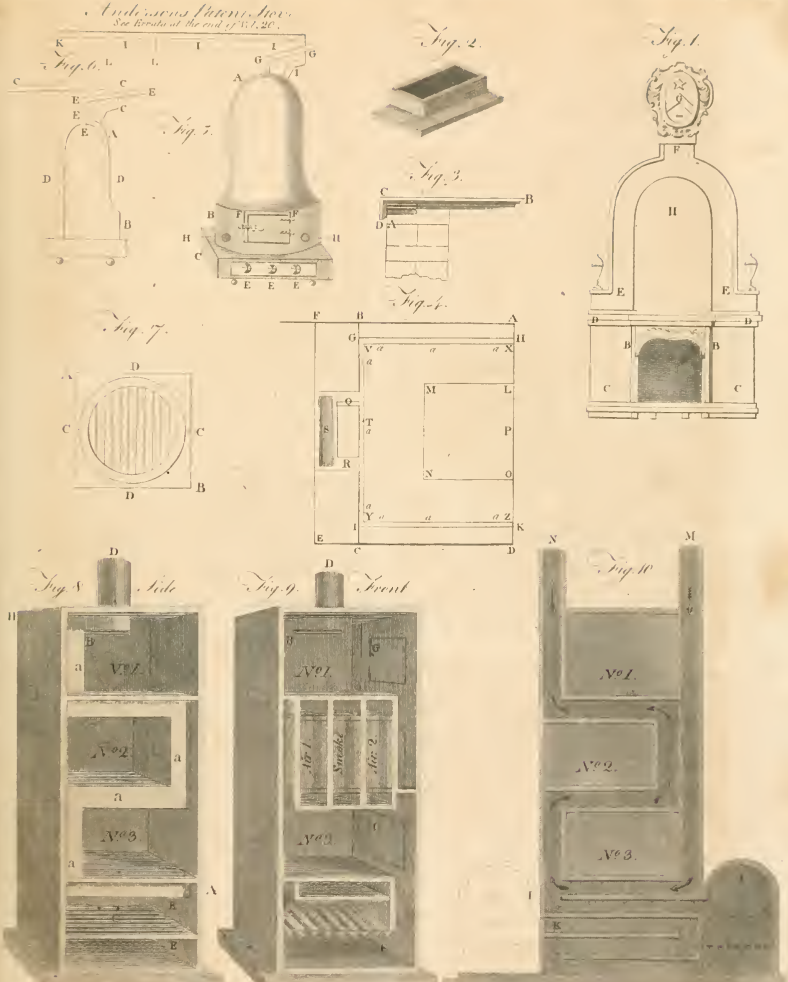
The ftove is managed as follows: Early in the morning the fuperintendant fhuts all the fliders, and fets a lamp (burning) in each of the trunks X and Z, and fhuts the doors. He then puts on and kindles the fire in the ftove, and manages it either in the Ruffian or German method. Perhaps the latter is preferable, as being liable to feweft accidents from miftake or neglect.

The lamps fet in the lower ends of the upright trunks prefently warm them, and produce a current of air upwards. This muft be fupplied by the horizontal trunk, which muft take it from the cafe round the ftove. Thus a current is begun in the direction we wifh. By and by the air in the cafe acquires heat from the ftove, and the current becomes extremely brifk. When the manager perceives this, he removes the lamps, fhuts the valves, and opens the holes *a*, *a*, &c. beginning with the moft remote, and proceeding flowly towards the ftove from each extremity of the horizontal branches. The heated air now iffues by thefe holes, glides along the ceiling below the galleries, and efcapes, by rifing up along the fronts of the galleries, and will be fenfibly felt by thofe fitting there, coming on their faces with a gentle warmth. It will then rife (in great part) ftraight up, while fome of it will glide backwards, to the comfort of thofe who fit behind.

The propriety of fhutting the valves of the upright trunks is evident. If they were left open, no air would come out by the holes *a*, *a*, &c.; but, on the contrary, the air would go in at thefe holes to fupply the current, and the ftove be rendered ufelefs. The air delivered by thefe holes will keep clofe to the ceiling, and will not, as we imagine, incommode thofe who fit below the galleries. But if it fhould be found to render thefe parts too warm, holes may be pierced through the ceiling, by which it will rife among the people above, and muft be very comfortable. It will require the careful attention of fome intelligent perfon to bring all this into a proper train at firft, by finding the proper apertures of the different holes, fo as to render the heat equable through the whole fpace. But this being once afcertained the difficulty is over.

The air trunks muft be very capacious, but may be contracted towards the extremities as their lateral difcharges diminifh; and the row of holes which admit the air to the cafe round the ftove muft be fully able to fupply them.

It muft be obferved, that in this conftruction the afcenfional force is but fmall. It is only the height of a fhort column of warm air from the ground to the galleries. At firft indeed it is great, having the unlimited height of the perpendicular trunks at X and Z; but during the ufe of the ftove it is reduced to nine or ten feet. It is neceffary, therefore, that the ftove be highly heated, perhaps confiderably beyond the Ruffian practice, but yet inferior to the heat of the German iron ftoves. But ftill we ftrongly recommend the brick or pottery ftoves, on account of the wholefome fweetnefs of the air which they furnifh; and we are certain that a ftove of moderate dimenfions, eight feet long, for inftance, by eight feet high, will be fufficient for warming a church holding 1200 or 1500 people. If the ftove could be placed lower, which in many fituations is very practicable, its effect would be proportionally greater, becaufe all depends on the rapidity of the current. When we are limited in height, we muft extend the ftove



Anderson's Patent Stove.

Stove. ſtove ſo much the more in length, and make the air trunks more capacious. Theſe and many other circumſtances of local modification muſt be attended to by the erector of the ſtove; and without the judicious attention of an intelligent artiſt, we may expect nothing but diſappointment. It is hardly poſſible to give inſtructions ſuited to every ſituation; but a careful attention to the general principle which determines the aſcenſional force will free the artiſt from any great riſk of failure.

We may ſay the ſame thing of ſtoves for conſervatories, hot-houſes, hot walls, &c. and can hardly add any thing of conſequence to what we have already ſaid on theſe heads in the article PNEUMATICS.

We muſt not, however, diſmiſs the ſubject without taking notice of the very ſpecious projects which have been frequently offered for drying malt by ſtoves. Many of theſe are to be ſeen in the publications of the Academies of Stockholm, Upſal, Copenhagen; and ſome have been erected in this kingdom, but they have not been found to anſwer.

We apprehend that they cannot anſwer. To dry malt, and make it fit for the ales and beers for which this iſland is ſo famous, it is by no means enough that we give it a proper and an equable ſupply of heat.—This alone would bake it and make it flinty, cauſing the moiſture to penetrate the mealy particles of the grain; and, by completely diſſolving the ſoluble parts, would render each kernel an uniform maſs, which would dry into a flinty grain, breaking like a piece of glaſs.—A grain of malt is not an inert pulp. It is a SEED, in an active ſtate, growing, and of an organized ſtructure. We wiſh to ſtop it in this ſtate, and kill it, not by heating it, but by abſtracting its moiſture. We thus leave it in its granulated or organized form, ſpungy, and fit for imbibing water in the maſh tub, without running into a paſte.

To accompliſh theſe purpoſes, the conſtruction of our malt kilns ſeems very well adapted. The kiln is the only flue of the furnace, and a copious *current* of air is formed through among the grains, carrying off with it the water which is evaporating by the heat. But this evaporation, being chiefly in conſequence of the vapour being immediately diſſolved by the paſſing air, will ſtop as ſoon as the current of air ſtops. This current has to make its way through moiſt grain, laid in a pretty thick bed, and matted together. Some force, therefore, is neceſſary to drive it through. This is furniſhed by the draught of the kiln. Subſtituting a ſtove, immediately applied to the malt, will not have this effect. The only way in which we think this can be done different from the preſent, is to have a horizontal flue, as has been propoſed in theſe projects, ſpread out at a ſmall diſtance below the grate on which the malt is laid, and to cover the whole with a high dome, like a glaſs-houſe dome. This being filled with a tall column of hot air, and having no paſſage into it but through the malt, would produce the current which we want. We are convinced that this will make much leſs fuel ſerve; but we are by no means certain that the ſulphureous and carbonic acid which accompanies the air in our common kiln is not a neceſſary or a uſeful ingredient in the proceſs. It is well known that different coaks, cinders, or charcoals, impart different qualities to the malts, and are preferred *each for its own purpoſe*.

A ſtove conſtructed on ſimilar principles, but compoſed of very different materials, has been lately erected in ſeveral of the churches in Edinburgh. This ſtove, which is formed entirely of caſt iron, may be conſidered as a double ſtove, an outer caſe, and a furnace or inner ſtove. The fuel is burnt in the inner ſtove; and the ſmoke produced during the proceſs of combuſtion, is carried off by a chimney, which paſſes through the top of the outer ſtove, and is conveyed to the outſide of the building. The outer caſe includes not only the furnace or inner ſtove, but alſo a conſiderable ſpace, occupied by the air of the atmoſphere, which is freely admitted through a number of openings placed around it; and when any current of air is produced, it paſſes off from the ſpace between the outer caſe and inner ſtove, and is conveyed by tubes through the body of the apartment. But we ſhall firſt deſcribe the different parts of which the ſtove is compoſed, after which we ſhall be better able to underſtand its mode of operation.

Fig. 5. exhibits a perſpective view of this ſtove. AB is the body, which is about three feet high, and of a circular form. BC is a ſquare pedeſtal on which the ſtove is placed, and which contains the aſh pit DD. The height of the pedeſtal is about a foot, and it is nearly inſulated by reſting on the ſpherical ſupports *a a*, alſo of caſt iron. EEE are openings in front of the aſh pit through which the air enters to ſupport the combuſtion. Theſe openings can be enlarged or diminiſhed, or opened and ſhut at pleaſure. FF is the door of the furnace through which the fuel is introduced. This door is attached to the inner furnace, and is double. It is one foot broad, and 11 inches high. GG is the chimney, which paſſes from the furnace within, through the outer caſe, and conveys the ſmoke out of the building. HH are openings in the outer caſe, and are eight in number, through which the air enters, and being heated, is greatly rarified, and paſſes off through the funnel or pipe IIII. This pipe communicates only with the outer ſtove, and being ſhut at the end K, the air ruſhes out from the ſmall tubes LL, inſerted into the ſide of the pipe IIII, and thus mixes with the cold air of the church. The diameter of the outer caſe at the bottom is about two feet, and the diameter of the furnace within is about 16 inches.

Fig. 6. is a ſection of the ſtove. AB is the outer caſe, from which paſſes off the pipe or funnel CCC, by which the heated air is conveyed through the church. DD is the furnace in the inſide, in which the fuel is burnt, and EEE is the chimney or funnel which conveys the ſmoke from the inner furnace out of the building. It paſſes through the outer ſtove AB at F.

Fig. 7. is a plan of this ſtove. AB is the pedeſtal on which it reſts, and which contains the aſh pit. CC is the outer caſe, and DD is the furnace within, in which are ſeen the tranſverſe bars which ſupport the fuel.

The length of the body of the church, in which two ſtoves of the form and dimenſions now deſcribed are erected, is about 60 feet, and the breadth is about 45 feet. The tubes IIII are conveyed along the lower edge of the gallery, about half the length of the church. The fires are lighted up about four or five o'clock on the Sunday morning, during the earlier part of the cold ſeaſon; but as the ſeaſon advances, it is uſual to light them up the night before. From this time till the congregation aſſemble for the afternoon ſervice, the furnaces are

are kept conſtantly ſupplied with fuel. By this management the air in the church is kept comfortably warm during the coldeſt ſeaſon of the year.

Theſe ſtoves, it appears to us, are ſuſceptible of ſome improvement, both in their conſtruction and in the places in which they are erected. With regard to the firſt circumſtance, an external coating of plaſter work, or of the ſame kind of materials as are uſed for coating the inſide of chemical furnaces, would be of ſome uſe in preventing an unneceſſary waſte of heat, as well as the diſagreeable ſmell which is ſometimes complained of, and which is ſuppoſed to ariſe from the combuſtion of light bodies floating in the air and drawn by the current to the heated metal; and with regard to the laſt, viz. the places in which they are erected, it is perfectly obvious that they ought to be as completely inſulated as poſſible, and particularly ought not to communicate with any body which is a good conductor of heat. Some of the ſtoves erected in the churches of Edinburgh, which we have examined, are faulty in this reſpect. One in particular is placed in cloſe contact with a gable wall.

The quantity of coals conſumed in two of theſe ſtoves in one of the churches of Edinburgh during the courſe of a ſeaſon, we have been informed, amounts to about five carts of 12 cwt. each; ſo that at the Edinburgh prices of coal, the expence for fuel for heating one of the churches is about 50 ſhillings. This being added to the expences of attendance, includes the whole expenditure, beſides ſome occaſional repairs which are required in heating a church of the above dimenſions.

The following is the deſcription of an improved ſtove by Mr Field of Newman Street London, in which, it is ſtated by the author, the various advantages of heating, boiling, ſteaming, evaporating, drying, ventilating, &c. are united; ſome of which we ſhall detail in his own words.

"Fig. 8. repreſents a longitudinal ſection of the ſtove, ſhowing the courſe of the air from its entrance into the flues of the ſtove at A, to its entrance into the upper chamber of the ſtove at B; and alſo the courſe of the ſmoke from the fire-place at C, till it eſcapes from the ſtove at D. E, E, are the doors or openings of the fire-place and aſh-hole.

"Fig. 9. is a ſimilar ſection at right angles with the above, exhibiting the courſe of the air through the chambers of the ſtove, from its entrance into the chamber N° 1. at B to its entrance beneath the fire-place at F. This figure alſo ſhows ſections of the flues, with the diviſions through which the air and ſmoke paſs ſeparately, the ſmoke-flue in the centre, and the air-flues on each ſide. G, G, are doors and openings through which the articles to be dried are introduced into the chambers.

"When the fire is lighted, and the doors of the chambers, aſh-hole, and fire-place, cloſed, the air by which the fire is ſupplied enters at A, fig 8. paſſes through the air-flues *a*, *a*, *a*, *a*, enters the upper chamber at B, traverſes and deſcends through the chambers N° 1, 2, 3, and arrives beneath the fire at F, fig. 9. Having ſupplied the fire with oxygen, it paſſes through the flue with the ſmoke, and eſcapes at D, heating in its protracted courſe the chambers and air-flues.

"As the cold air enters the ſtove at A, immediately above a plate forming the top of the fire-place, and purſues a ſimilar route with the fire-flue, it enters the chambers very much heated and rarefied. Hence any moiſt ſubſtance placed in the chambers evaporates in conſequence, not only of the heated flues circulating round them, but of a ſtream of warm rarefied air, which, while it continually raiſes evaporation, as continually bears away the exhaled moiſture in its paſſage to the fire, thus imitating the gradual and efficacious plan of nature in drying by the ſun and air. While theſe effects are taking place within the ſtove, part of the air which enters at A, fig. 8. and 9. paſſes through air-flues on the other ſide of the fire-flue, purſues a parallel courſe with the firſt, and gives out a current of warm air to the room at an aperture H. This effect may be obtained in a much higher degree, if the doors of the chambers and aſh-hole are opened: ſhould the hand or face be then brought near, they would be fanned with a ſtream of warm air, eſpecially from the upper chamber.

"By means of this ſtove I have evaporated milk to dryneſs, without burning or diſcolouring it; and have dried cherries, plums, and other fruits, ſo as to imitate thoſe which are received from abroad. I have repeatedly dried colours and the moſt delicate ſubſtances without the ſlighteſt injury, even though the operation proceeded quickly.

"The height of the ſtove is about five feet and a half; its diameter two feet and a half, and that of the flues four inches. The external part is conſtructed of brick, and the internal parts of thin Ryegate or fire-ſtone, except the top of the fire-place, which is a plate of caſt iron. Were it to be wholly formed of iron, its effects would neceſſarily be more powerful.

"Fig. 10. repreſents an extenſion of the plan, in which ſtoves of this kind may be advantageouſly connected with one or more furnaces for chemical or other uſes. The fire-place, brought out, either in front or on one ſide, by the preſent poſitions of its crown I, forms a reverberatory furnace, or will make a ſand-bath by reverſing it.

"The ſpace occupied by the fire-place in fig. 8. may in this be converted into apartments for evaporating ſubſtances, or occaſionally for cooling them by an opening at K to admit cold air, while the warm air of the ſtove is excluded by a regiſter or door. The dotted lines ſhow the manner in which a ſecond furnace may be connected by an opening into the flue at L.

"In addition to the uſes already pointed out, this ſtove would probably be found extremely ſerviceable in drying japanners goods, and conſuming the noxious fumes and gas which ariſe from the oil and varniſh uſed in this buſineſs.

"Since the ſtove is not limited to any certain dimenſions, it might be adapted to the drying of malt and hops, perhaps of herbs, corn, and ſeeds generally. It might alſo be accommodated to the purpoſes of the ſugar-bakers, connected with the great fires they employ for their boilers. It has been ſhown to be uſeful in the confectioners art, and probably it may be equally ſo in baking biſcuits for the navy; nor leſs ſo in drying linen for the laundreſs, dyer, calico-printer, and bleacher. I have myſelf found it well accommodated for a chemical elaboratory *."

* Phil. Mag. vol. xxvii.

STOURBRIDGE, or STURBICH, the name of a field near Cambridge, noted for its famous fair kept annually on the 7th of September, and which continues for a fortnight. The commodities are, horſes, hops, iron, wool, leather, cheeſe, &c. This place is alſo noted

noted for an excellent species of clay capable of resisting an intense heat. It is used in making pots for glass-houses, fire-bricks, &c.; and is sold at an high price.

STOW, the name of a market-town in Gloucestershire in England, situated in W. Long. 1. 50. N. Lat. 51. 54. It is also the name of a fine seat of the marquis of Buckingham in Buckinghamshire. Here are the best gardens in England, adorned with busts, statues, obelisks, pavilions, and temples. It is two miles from the town of Buckingham.

STOW, *John*, the industrious historian, son of Thomas Stow merchant-taylor of St Michael's, Cornhill, in London, was born about the year 1525. Of the early part of his life we know very little, except that he was bred to his father's business, which in the year 1560 he relinquished, devoting himself entirely to the study of our ancient historians, chronicles, annals, charters, registers, and records. Of these he made a considerable collection, travelling for that purpose to different parts of the kingdom, and transcribing such manuscripts as he could not purchase. But this profession of an antiquary being attended with no present emolument, he was obliged for subsistence to return to his trade.—It happened, however, that his talents and necessities were made known to Dr Parker archbishop of Canterbury; who being himself an antiquary, encouraged and enabled Mr Stow to prosecute his darling study. In those times of persecution, though Elizabeth was then upon the throne, honest John Stow did not escape danger. His collection of Popish records was deemed cause of suspicion. His younger brother Thomas preferred no less than 140 articles against him before the ecclesiastical commission; but the proof being insufficient, he was acquitted. In 1565 he first published his Summary of the Chronicles of England. About the year 1584 he began his Survey of London. In 1585 he was one of the two collectors for a great muster of Limestreet ward: in the same year he petitioned the corporation of London to bestow on him the benefit of two freemen, to enable him to publish his survey; and in 1589 he petitioned again for a pension. Whether he succeeded, is not known. He was principally concerned in the second edition of Holinshed's chronicle, published in 1587. He also corrected, and twice augmented, Chaucer's works, published in 1561 and in 1597. His survey of London was first published in 1598. To these laborious works he would have added his large Chronicle, or History of England; but he lived only to publish an abstract of it, under the title of *Flores Historiarum*. The folio volume, which was printed after his death, with the title of *Stow's Chronicle*, was taken from his papers by Edmund Howes. Having thus spent his life and fortune in these laborious pursuits, he was at last obliged to solicit the charitable and well disposed for relief. For this purpose, King James I. granted him, in 1603, a brief, which was renewed in 1604, authorizing him to collect in churches the benefactions of his fellow-citizens. He died in April 1605, aged 80; and was buried in his parish church of St Andrew's, Undershaft, where his widow erected a decent monument to his memory. John Stow was a most indefatigable antiquarian, a faithful historian, and an honest man.

STOWMARKET, a town of Suffolk, in England, situated in E. Long. 1. 6. N. Lat. 52. 16. It is a large handsome place, situated between the branches of the rivers Gypping and Orwell, and is remarkable for having the best cherries in England.

STOWAGE, the general disposition of the several materials contained in a ship's hold, with regard to their figure, magnitude, or solidity.

In the stowage of different articles, as ballast, casks, cases, bales, and boxes, there are several general rules to be observed, according to the circumstances or qualities of those materials. The casks which contain any liquid are, according to the sea phrase, to be *bung-up* and *bilge-free*, i. e. closely wedged up in an horizontal position, and resting on their quarters: so that the bilges where they are thickest being entirely free all round, cannot rub against each other by the motion of the vessel. Dry goods, or such as may be damaged by the water, are to be carefully inclosed in casks, bales, cases, or wrappers; and wedged off from the bottom and sides of the ship, as well as from the bow, masts, and pump-well. Due attention must likewise be had to their disposition with regard to each other, and to the trim and centre of gravity of the ship; so that the heaviest may always be nearest the keel, and the lightest gradually above them.

STRABISMUS, squinting. See MEDICINE *Index*.

STRABO, a celebrated Greek geographer, philosopher, and historian, was born at Amasia, and was descended from a family settled at Gnossus in Crete. He was the disciple of Xenarchus, a Peripatetic philosopher, and at length attached himself to the Stoics. He contracted a strict friendship with Cornelius Gallus, governor of Egypt, and travelled into several countries to observe the situation of places, and the customs of nations. He flourished under Augustus, and died under Tiberius about the year 25, in a very advanced age.—He composed several works, all of which are lost except his Geography in 17 books; which are justly esteemed very precious remains of antiquity. The two first books are employed in showing, that the study of geography is not only worthy of, but even necessary to, a philosopher; the third describes Spain; the fourth, Gaul and the Britannic isles; the fifth and sixth, Italy and the adjacent isles; the seventh, which is imperfect at the end, Germany, the countries of the Getæ and Illyrii, Taurica Chersonesus, and Epirus; the eighth, ninth, and tenth, Greece with the neighbouring isles; the four following, Asia within Mount Taurus; the fifteenth and sixteenth, Asia without Taurus, India, Persia, Syria, Arabia; and the seventeenth, Egypt, Æthiopia, Carthage, and other places of Africa. Strabo's work was published with a Latin version by Xylander, and notes by Isaac Casaubon, (or rather by Henry Scrimzeer, from whom Casaubon chiefly stole them), at Paris, 1620, in folio. But the best edition is that of Amsterdam in 1707, in two volumes folio, by the learned Theodore Jansonius ab Almelooveen, with the entire notes of Xylander, Casaubon, Meursius, Cluver, Holstenius, Salmasius, Bochart, Ez. Spanheim, Cellarius, and others. To this edition is subjoined the *Chrestomathiæ*, or epitome of Strabo; which according to Mr Dodwell, who has written a very elaborate and learned dissertation about it, was made by some unknown person between the years of Christ 676 and 996. It has been found of some use,

 not

not only in helping to correct the original, but in supplying in some measure the defect in the seventh book. Mr Dodwell's dissertation is prefixed to this edition.

STRADA, Famianus, a very ingenious and learned Jesuit, was born at Rome in the latter end of the 16th century, and taught rhetoric there, in a public manner, for fifteen years. He wrote several pieces upon the art of oratory, and published some orations with a view of illustrating by example what he had inculcated by precept. But his *Prolusiones Academicæ* and his *Historia de Bello Belgico* are the works which raised his reputation, and have preserved his memory. His history of the war of Flanders was published at Rome; the first decad in 1640, the second in 1647; the whole extending from the death of Charles V. which happened in 1558, to the year 1590. It is written in good Latin, as all allow; but its merit in other respects has been variously determined. His *Prolusiones Academicæ* show great ingenuity, and a masterly skill in classical literature; that prolusion especially in which he introduces Lucan, Lucretius, Claudian, Ovid, Statius, and Virgil, each of them versifying according to his own strain. They have been often printed. We know not the year of Strada's birth or of his death.

STRAHAN, William, an eminent printer, was born at Edinburgh in the year 1715. His father, who had a small appointment in the customs, gave his son the education which every one of decent rank then received in a country where the avenues to learning were easy, and open to men of the most moderate circumstances. After having passed through the tuition of a grammar school, he was put apprentice to a printer; and when a very young man, removed to a wider sphere in that line of business, and went to follow his trade in London. Sober, diligent, and attentive, while his emoluments were for some time very scanty, he contrived to live rather within than beyond his income; and though he married early, and without such a provision as prudence might have looked for in the establishment of a family, he continued to thrive, and to better his circumstances. This he would often mention as an encouragement to early matrimony; and used to say, that he never had a child born that Providence did not send some increase of income to provide for the increase of his household. With sufficient vigour of mind, he had that happy flow of animal spirits that is not easily discouraged by unpromising appearances.

His abilities in his profession, accompanied with perfect integrity and unabating diligence, enabled him, after the first difficulties were overcome, to advance with rapid success. And he was one of the most flourishing men of the trade, when, in the year 1770, he purchased a share of the patent for king's printer of Mr Eyre, with whom he maintained the most cordial intimacy during the rest of his life. Beside the emoluments arising from this appointment, as well as from a very extensive private business, he now drew largely from a field which required some degree of speculative sagacity to cultivate on account of the great literary property which he acquired by purchasing the copy-rights of the most celebrated authors of the time. In this his liberality kept pace with his prudence, and in some cases went perhaps rather beyond it. Never had such rewards been given to the labours of literary men as now were received from him and his associates in those purchases of copy-rights from authors.

Having now attained the first great object of business, wealth, Mr Strahan looked with a very allowable ambition on the stations of political rank and eminence, Politics had long occupied his active mind, which he had for many years pursued as his favourite amusement, by corresponding on that subject with some of the first characters of the age. Mr Strahan's queries to Dr Franklin in the year 1769, respecting the discontents of the Americans, published in the London Chronicle of 28th July 1778, show the just conception he entertained of the important consequences of that dispute, and his anxiety as a good subject to investigate, at that early period, the proper means by which their grievances might be removed, and a permanent harmony restored between the two countries, In the year 1775 he was elected a member of parliament for the borough of Malmsbury in Wiltshire, with a very illustrious colleague, the Hon. C. J. Fox; and in the succeeding parliament, for Wootton Basset, in the same county. In this station, applying himself with that industry which was natural to him, he was a useful member, and attended the house with a scrupulous punctuality. His talents for business acquired the consideration to which they were intitled, and were not unnoticed by the minister.

In his political connection he was constant to the friends to whom he had first been attached. He was a steady supporter of that party who were turned out of administration in spring 1784, and lost his seat in the house of commons by the dissolution of parliament with which that change was followed: a situation which he did not shew any desire to resume on the return of the new parliament; arising from a feeling of some decline in his health, which had rather suffered from the long sittings and late hours with which the political warfare in the preceding had been attended. Without any fixed disease, his strength visibly declined; and though his spirits survived his strength, yet the vigour and activity of his mind were considerably impared. Both continued gradually to decline till his death, which happened on the 9th of July 1785 in the 71st year of his age.

Endued with much natural sagacity, and an attentive observation of life, he owed his rise to that station of opulence and respect which he attained, rather to his own talents and exertion, than to any accidental occurrence of favourable or fortunate circumstances. His mind was not uninformed by letters; and from a habit of attention to style, he acquired a considerable portion of critical acuteness in the discernment of its beauties and defects? In one branch of writing he particularly excelled—the epistolary; in which he not only showed the precision and clearness of business, but possessed a neatness as well as a fluency of expression which few letter-writers have been known to surpass. Letter-writing was one of his favourite amusements; and among his correspondents were men of such eminence and talents as well repaid his endeavours to entertain them. Among these, as before mentioned, was the justly celebrated Dr Franklin, originally a printer like Mr Strahan, whose friendship and correspondence, notwithstanding the difference of their sentiments in political matters,

he

he continued to enjoy till his death. One of the lateſt letters which he received from his illuſtrious and venerable friend contained a humorous allegory of the ſtate of politics in Britain, drawn from the profeſſion of printing; of which, though the doctor had quitted the exerciſe, he had not forgotten the terms.

The judicious diſpoſition which Mr Strahan made of his property, affords an evident proof of his good ſenſe and propriety. After providing munificently for his widow and children, his principal ſtudy ſeems to have been to mitigate the affliction of thoſe (and many there were) who would more immediately have felt his loſs, by bequeathing them liberal annuities for their lives; and (recollecting that all of a profeſſion are not equally provident) he left 1000l. to the Company of Stationers, the intereſt to be divided among infirm old printers.

As the virtuous connections of the life and the heart are always pleaſing to trace,—of Mr Strahan it may briefly be ſaid, that his capacity, diligence, and probity, raiſed him to the head of his profeſſion. The good humour and obliging diſpoſition which he owed to nature, he cultivated with care, and confirmed by habit. His ſympathetic heart beat time to the joy and ſorrow of his friends. His advice was always ready to direct youth, and his purſe open to relieve indigence. Living in times not the pureſt in the Engliſh annals, he eſcaped unſullied through the artifices of trade and the corruption of politics. In him a ſtrong natural ſagacity, improved by an extenſive knowledge of the world, ſerved only to render reſpectable his unaffected ſimplicity of manners, and to make his Chriſtian philanthropy more diſcerning and uſeful. The uninterrupted health and happineſs which accompanied him for half a century in the capital, proves honeſty to be the beſt policy, temperance the greateſt luxury, and the eſſential duties of life its moſt agreeable amuſement. In his elevated fortune, none of his former acquaintance ever accuſed him of neglect. He attained proſperity without envy, enjoyed wealth without pride, and diſpenſed bounty without oſtentation.

STRAIKS, in the military art, are ſtrong plates of iron, ſix in number, fixed with large nails called *ſtraik-nails*, on the circumference of a cannon-wheel, over the joints of the fellows; both to ſtrengthen the wheel, and to ſave the fellows from wearing on hard ways or ſtreets.

STRAIN, a pain occaſioned by the violent extenſion of ſome membranous or tendinous part.

STRAIN, *Streſs*, in *Mechanics*, are terms indiſcriminately uſed to expreſs the force which is *excited* in any part of a machine or ſtructure of any kind tending to break it in that part. Thus every part of a rope is *equally* ſtrained by the weight which it ſuſpends. Every part of a pillar is *equally* ſtrained by the load which it ſupports. A mill axle is *equally* twiſted and ſtrained in every part which lies between the part of the wheel actuated by the moving power and the part which is reſiſted by the work to be performed. Every part of a lever or joiſt is *differently* ſtrained by a force acting on a diſtant part.

It is evident that we cannot make the ſtructure fit for its purpoſe, unleſs the ſtrength at every part be at leaſt equal to the ſtreſs laid on, or the ſtrain excited in that part. It is no leſs plain, that if we are ignorant of the principles which determine this ſtrain, both in intenſity and direction, in relation to the magnitude and the ſituation of its remote cauſe, the only ſecurity we have for ſucceſs is to give to every part of the aſſemblage ſuch ſolidity that we can leave no doubt of its ſufficiency. But daily experience ſhows us that this vague ſecurity is in many caſes uncertain, if we are thus ignorant. In all caſes it is ſlovenly, unlike an artiſt, attended with uſeleſs expence, and in machines is attended with a loſs of power which is waſted in changing the motions of a needleſs load of matter.

It muſt therefore greatly tend to the improvement of all profeſſions occupied in the erection or employment of ſuch ſtructures, to have a diſtinct notion of the ſtrains to which theſe parts are expoſed. Frequently, nay generally, theſe ſtrains are not immediate, but ariſe from the action of forces on diſtant parts, by which the aſſemblage is ſtrained, and there is a tendency to rupture in every part. This ſtrain is *induced* on every part, and is there modified by fixed mechanical laws. Theſe it is our buſineſs to learn; but our chief object in this inveſtigation is to determine the ſtrength of materials which it is neceſſary to oppoſe in every part to this ſtrain; and how to oppoſe this ſtrength in ſuch a manner that it ſhall be exerted to the beſt advantage. The notions of ſtrain and ſtrength therefore hardly admit of ſeparation; for it is even by means of the ſtrength of the intermediate parts that the ſtrain is propagated to, or excited in, the part under conſideration. It is proper therefore to conſider the whole together under the article *STRENGTH of Materials* in mechanics.

STRAINING, is the clarification of a liquor, by paſſing it through a ſieve or filter. The word is derived from the French, *eſtreindre;* which is formed from *ex*, "out of," and *ſtringere*, "to preſs."

STRAIT, a narrow channel or arm of the ſea, ſhut up between lands on either ſide, and affording a paſſage out of one great ſea into another.

There are three kinds of ſtraits. 1. Such as join one ocean to another. Of this kind are the ſtraits of Magellan and Le Maire. 2. Thoſe which join the ocean to a gulf: the ſtraits of Gibraltar and Babelmandel are of this kind, the Mediterranean and Red ſea being only large gulfs. 3. Thoſe which join one gulf to another; as the ſtraits of Caffa, which join the Palus Mæotis to the Euxine or Black ſea. The paſſage of ſtraits is commonly dangerous, on account of the rapidity and oppoſite motion of currents. The moſt celebrated ſtrait in the world is that of Gibraltar, which is about from 24 to 36 miles long, and from 15 to 24 broad, joining the Mediterranean ſea with the Atlantic ocean. The ſtraits of Magellan, diſcovered in 1520 by F. Magellan, were uſed ſome time as a paſſage out of the North into the South ſea; but ſince the year 1616, that the ſtrait of Le Maire has been diſcovered, the former has been diſuſed; both becauſe of its length, which is full three hundred miles, and becauſe the navigation thereof is very dangerous, from the waves of the North and South ſeas meeting in it and claſhing. The ſtrait at the entrance of the Baltic is called the *Sound;* that between England and France, *Le pas de Calais*, or the *Channel*. There are alſo the ſtraits of Weigats, of Jeſſo, of Anian, of Davis, and Hudſon, &c.

STRAKES, or STREAKS, in a ſhip, the uniform ranges of planks on the bottom and ſides of a ſhip, or the continuation of planks joined to the ends of each other,

other, and reaching from the ftem to the ftern-poft and fafhion-pieces; the loweft of thefe, which is called the *garboard-ftreak*, is let into the keel below, and into the ftem and ftern-poft. They fay alfo a *fhip heels a ftrake*, that is, hangs or inclines to one fide the quantity of a whole plank's breadth.

Strakes, or *ftreks*, in mining, are frames of boards fixed on or in the ground, where they wafh and drefs the fmall ore in a little ftream of water, hence called *ftraked ore*.

STRALSUND, a ftrong and rich fea-port town of Germany, in Hither Pomerania, formerly an important trading-place. In 1678 it was forced to furrender to the elector of Brandenburg, after 1800 houfes had been burnt to afhes in one night's time. After this the Swedes defended it to the laft extremity; and Chas. XII. in 1714, came hither after his return out of Turkey. But the thrown of Sweden not being able to hold out againft five great powers, it was forced to fubmit in 1715. In 1720 it was rendered back to Sweden, but in a very poor condition. It is almoft furrounded by the fea and the lake Francen, and has a harbour feparated from the ifle of Rugen by a narrow ftrait. It is 15 miles northweft of Grippfwald, and 40 north-eaft of Guftrow. E. Long. 13. 28. N. Lat. 54 17.

STRAMONIUM, a fpecies of plant. See Datura, Botany *Index*.

STRAND (*Saxon*), any fhore or bank of a fea or great river. Hence the ftreet in the weft fuburbs of London, which lay next the fhore or bank of the Thames, was called the *Strand*. An immunity from cuftom, and all impofitions upon goods or veffels by land or water, was ufually expreffed by *ftrand* or *ftream*.

STRANDED (from the Saxon *ftrand*), is when a fhip is by tempeft, or by ill fteerage, run on ground, and fo perifhes. Where a veffel is ftranded, juftices of the peace, &c. fhall command conftables near the fea-coafts to call affiftance for the prefervation of the fhip; and officers of men of war are to be aiding and affifting thereto.

STRANGE, Sir Robert, an eminent engraver, who carried the art to great perfection in this country, and was diftinguifhed not only as an artift, but highly refpected and beloved on account of his private virtues and domeftic habits. Modeft as he was ingenious, he ufed to fay that the works of an artift fhould ferve for his life and monument. His works no doubt will perpetuate his name whilft any tafte for the fine arts remains.

Sir Robert Strange was born in the ifland of Pomona in Orkney, July the 14th 1721; and died at London July the 5th 1792. He was lineally defcended from David Strange or Strang, a younger fon of the family of the Stranges or Strangs of Balcafky, in the county of Fife, who fettled in Orkney at the time of the Reformation. But as there were no males remaining of the elder branch of the Stranges of Balcafky, Sir Robert became the male reprefentative of it, and was found by a legal inveftigation to have a right to the armorial bearings and every other mark of honour belonging to that ancient family.

He received his claffical education at Kirkwall in Orkney, under the care of a learned, worthy, and much refpected gentleman, Mr Murdoch Mackenzie, who has rendered infinite fervice to his country by the accurate furveys and charts he has given of the iflands of Orkney, and of the Britifh and Irifh coafts.

Originally intended for the law, Mr Strange foon became tired of that profeffion, and perceived that his genius decifively led him to the arts of drawing and engraving. For this purpofe he was introduced to the late Mr Richard Cooper at Edinburgh, the only perfon there who had then any tafte in that line of the fine arts. He was bound with him as an apprentice for fix years; during which time he made fuch progrefs in his new profeffion, that his friends entertained the higheft expectation of his fuccefs; nor were they difappointed.

In the year 1747 he married Ifabella, only daughter of William Lumifden, fon of Bifhop Lumifden; and foon after his marriage he went to France, where with the moft ardent application he profecuted his ftudies, chiefly at Paris, under the direction of the celebrated Le Bas, who engraved many excellent prints from the Dutch painters. It was from Le Bas he had the firft hint of the ufe of the inftrument commonly called *the dry needle*; but which he afterwards greatly improved by his own genius, and which has added fuch fuperior beauties to his engravings.

In the year 1751 Mr Strange removed with his family from Edinburgh and fettled at London, where he engraved feveral fine hiftorical prints, which juftly acquired to him great reputation. At this period hiftorical engraving had made little progrefs in Britain, and he may be properly confidered as its father.

The admiration he always had for the works of the great Italian painters made him long defire to vifit Italy, the feat of the fine arts; and the farther he advanced in life, he became the more perfuaded that a journey to that country was effential to an artift who had the laudable ambition to excel in his profeffion. He therefore undertook this journey in the year 1760. In Italy he made many admirable drawings, feveral of which he afterwards engraved. Thefe drawings are now in the poffeffion of Lord Dundas.

Everywhere in Italy fingular marks of attention were beftowed on Mr Strange; not only by great perfonages, but by the principal academies of the fine arts in that country. He was made a member of the academies of Rome, Florence, and Bologna, and profeffor in the royal academy at Parma.

To fhow the eftimation in which his talents were held at Rome, we cannot but record the following anecdote. The ceiling of the room of the Vatican library, in which the collection of engravings is kept, is elegantly painted by Signor Rotfanelli. It reprefents the progrefs of engraving; and the portraits of the moft eminent artifts in that line are there introduced, among which is that of our artift. Under his arm he holds a portfolio, on which his name is infcribed. He is the only Britifh artift on whom this honour has been conferred.

In France, where he refided many years at different periods, his talents likewife received every mark of attention that could be beftowed on a foreigner. He was made a member of the royal academy of painting at Paris.

His majefty King George III. ever attentive to the progrefs of the fine arts in Britain, and fenfible of the advantages of which engraving particularly has been to this

this country, even in a commercial light; and desirous to give a mark of his royal approbation of the merit of Mr Strange, whom he considered as at the head of his profession and the great improver of it—was graciously pleased to confer the honour of knighthood on him the 5th of January 1787.

Such was Sir Robert Strange as an artist; nor was he less distinguished by his truly amiable moral qualities, which endeared him to all who had the happiness to know him.

With regard to his works, he left fifty capital plates, still in good condition, which are carefully preserved in his family. They are engraved from pictures by the most celebrated painters of the Roman, Florentine, Lombard, Venetian, and other schools. They are historical, both sacred and profane, poetical, allegorical.

From his earliest establishment in life, Sir Robert carefully preserved about eighty copies of the finest and most choice impressions of each plate he engraved; which, from length of time, have acquired a beauty, mellowness, and brilliancy, easier seen than described. He did this with a view of presenting them to the public at a period when age should disable him from adding to their number. These he collected into as many volumes, and arranged them in the order in which they were engraved. To each volume he prefixed two portraits of himself, on the same plate, the one an etching, the other a finished proof, from a drawing by John Baptiste Greuse. This is the last plate which he engraved; and is a proof that neither his eyes nor hand were impaired by age. It likewise shows the use he made both of aquafortis and the graver. Each volume, besides a dedication to the king, contains an introduction on the progress of engraving, and critical remarks on the pictures from which his engravings are taken. These volumes were ready to be given to the public, when Sir Robert's death delayed this magnificent publication; a publication which does so much honour to the artist, and to the country which gave him birth. He died at London 5th July 1792.

The following is an authentic catalogue of his works. Plate 1. Two Heads of the author—one an etching, the other a finished proof, from a drawing by John Baptiste Greuse; 2. The Return from Market, by Wouvermans; 3. Cupid, by Vanloo; 4. Mary Magdalen, by Guido; 5. Cleopatra, by the same; 6. The Madonna, by the same; 7. The Angel Gabriel, by the same; 8. The Virgin, holding in her hand a book, and attended by angels, by Carlo Maratt; 9. The Virgin with the Child asleep, by the same; 10. Liberality and Modesty, by Guido; 11. Apollo rewarding Merit and punishing Arrogance, by Andrea Sacchi; 12. The Finding of Romulus and Remus, by Pietro da Cortona; 13. Cæsar repudiating Pompeia, by the same; 14. Three Children of King Charles I. by Vandyke; 15. Belisarius, by Salvator Rosa; 16. St Agnes, by Dominichino; 17 The Judgement of Hercules, by Nicolas Poussin; 18. Venus attired by the Graces, by Guido; 19. and 20. Justice and Meekness, by Raphael; 21. The Offspring of Love, by Guido; 22. Cupid Sleeping, by the same; 23. Abraham giving up the Handmaid Hagar, by Guercino; 24. Esther a Suppliant before Ahasuerus, by the same; 25. Joseph and Potiphar's Wife, by Guido; 26 Venus Blinding Cupid, by Titian; 27. Venus, by the same; 28. Danae, by the same; 29. Portrait of King Charles I. by Vandyke; 30. The Madonna, by Correggio; 31. St Cæcilia, by Raphael; 32. Mary Magdalen, by Guido; 33. Our Saviour appearing to his Mother after his Resurrection, by Guercino; 34. A Mother and Child, by Parmegiano; 35. Cupid Meditating, by Schidoni; 36. Laomedon King of Troy detected by Neptune and Apollo, by Salvator Rosa; 37. The Death of Dido, by Guercino; 38. Venus and Adonis, by Titian; 39. Fortune, by Guido; 40. Cleopatra, by the same; 41. Two Children at School, by Schidoni; 42. Mary Magdalen, by Correggio; 43. Portrait of King Charles I. attended by the marquis of Hamilton, by Vandyke; 44. Queen Henrietta, attended by the Prince of Wales, and holding in her arms the Duke of York, by the same; 45. Apotheosis of the Royal Children, by West; 46. The Annunciation, by Guido; 47. Portrait of Raphael Sancio D'Urbino, by himself; 48. Sappho, by Carlo Dolci; 49. Our Saviour asleep, by Vandyke; 50. St John in the Desert, by Murillo.

STRANGER, in *Law*, denotes a person who is not privy or party to an act. Thus a stranger to a judgement is he to whom a judgement does not belong; in which sense the word stands directly opposed to party or privy.

STRANGLES, in *Farriery*. See that article, N° 481.

STRANGURY, a suppression of urine. See MEDICINE *Index*.

STRAP, among surgeons, a sort of band used to stretch out limbs in the setting of broken or disjointed bones.

STRAP, in a ship, the rope which is spliced about any block, and made with an eye to fasten it anywhere on occasion.

STRAPS, in the manege. The straps of a saddle are small leather straps, nailed to the bows of the saddle, with which we make the girths fast to the saddle.

STRAPADO, or STRAPPADO, a kind of military punishment, wherein the criminals hands being tied behind him, he is hoisted up with a rope to the top of a long piece of wood, and let fall again almost to the ground; so that, by the weight of his body in the shock, his arms are dislocated. Sometimes he is to undergo three strapadoes or more.

STRASBURG, an ancient, large, handsome, and strong city of France, in Alsace, with a population of 40,000. It contains about 200 streets, part of which are very narrow, and most of the houses are built after the ancient taste. However, there are a great number of handsome buildings, such as the hotel of the marshal of France, who is commander of the city; the hotel of the cardinal of Rouen, the bishop's palace, the Jesuits college, the royal hospital, the hotel of Hesse-Darmstadt, the arsenal, the town-house, and the cathedral. It has a wooden bridge over the Rhine, which is thought to be one of the finest in Europe; as is likewise the cathedral church, whose tower is the handsomest in Germany, and the clock is greatly admired by all travellers. Some look upon it as one of the wonders of the world, and the steeple is allowed to be the highest in Europe. The clock not only shows the hours of the day, but the motion of the sun, moon, and stars. Among other things there is an angel, which turns an hour-

hour-glaſs every hour; and the twelve apoſtles proclaim noon, by each of them ſtriking a blow with a hammer on a bell. There is likewiſe a cock, which is a piece of clock-work, that crows every hour. There are 700 ſteps up to the tower or ſteeple, it being 500 feet high. It was a free and imperial city; but the king of France became maſter of it in 1681, and greatly augmented the fortifications, though before it had 365 cannon. The inhabitants were formerly Proteſtants, and carried on a great trade; but moſt of them have been obliged to embrace the Romiſh ſuperſtition, though there is ſtill a ſort of toleration. Such was Straſburg before the French revolution; what it is now we have not leiſure to inquire. It is ſeated on the river Ill, 55 miles north of Baſil, 112 ſouth-weſt of Mentz, and 255 eaſt of Paris. E. Long. 7. 51. N Lat. 48. 35.

STRATA, in *Natural Hiſtory*, the ſeveral beds or layers of different matters whereof the earth is compoſed. See GEOLOGY.

The ſtrata whereof the earth is compoſed are ſo very different in different countries, that it is impoſſible to ſay any thing concerning them that may be generally applicable: and indeed the depths to which we can penetrate are ſo ſmall, that only a very few can be known to us at any rate; thoſe that lie near the centre, or even a great way from it, being for ever hid. One reaſon why we cannot penetrate to any great depth is, that as we go down the air becomes foul, loaded with pernicious vapours, inflammable air, fixed air, &c. which deſtroy the miners, and there is no poſſibility of going on. In many places, however, theſe vapours become pernicious much ſooner than in others, particularly where ſulphureous minerals abound, as in mines of metal, coal, &c.

But however great differences there may be among the under ſtrata, the upper one is in ſome reſpects the ſame all over the globe, at leaſt in this reſpect, that it is fit for the ſupport of vegetables, which the others are not, without long expoſure to the air. Properly ſpeaking, indeed, the upper ſtratum of the earth all round, is compoſed of the pure vegetable mold, though in many places it is mixed with large quantities of other ſtrata, as clay, ſand, gravel, &c.; and hence proceed the differences of ſoils ſo well known to thoſe who practiſe agriculture.

It has been ſuppoſed, by ſome naturaliſts, that the different ſtrata of which the earth is compoſed were originally formed at the creation, and have continued in a manner immutable ever ſince: but this cannot poſſibly have been the caſe, ſince we find that many of the ſtrata are ſtrangely intermixed with each other; the bones of animals both marine and terreſtrial are frequently found at great depths in the earth; beds of oyſter-ſhells are found of immenſe extent in ſeveral countries; and concerning theſe and other ſhell-fiſh, it is remarkable, that they are generally found much farther from the ſurface than the bones or teeth either of marine or terreſtrial animals. Neither are the ſhells or other remains of fiſh found in thoſe countries adjoining to the ſeas where they grow naturally, but in the moſt diſtant regions. Mr Whitehurſt, in his Inquiry into the Original State and Formation of the Earth, has given the following account of many different kinds of animals, whoſe ſhells and other remains or *exuviæ* are found in England; though at preſent the living animals are not to be found except in the Eaſt and Weſt Indies.

A CATALOGUE of EXTRANEOUS FOSSILS, ſhowing where they were dug up; alſo their native Climates. Moſtly ſelected from the curious Cabinet of Mr NEILSON, in King-ſtreet, Red-Lion Square.

Their names, and Places where found.	Native Climates.
CHAMBERED NAUTILUS. Sheppy iſlands; Richmond in Surrey; Sherbone in Dorſetſhire, -	*Chineſe Ocean, and other Parts of that great ſea.*
TEETH OF SHARKS. Sheppy iſland, Oxfordſhire, Middleſex, Surrey, Northamptonſhire, -	*Eaſt and Weſt Indies.*
SEA-TORTOISE, ſeveral kinds; the *Hawkſbill, Loggerhead, and Green* ſpecies. Sheppy iſland, -	*Weſt Indies.*
MANGROVE TREE OYSTERS. Sheppy iſland, - - - -	*Weſt Indies.*
COXCOMB TREE OYSTERS. Oxfordſhire, Glouceſterſhire, Dorſetſhire, and Hanover, -	*Coaſt of Guinea.*
VERTEBRÆ *and* PALATES *of the* ORBES. Sheppy iſland, and many other parts of England, -	*Eaſt and Weſt Indies.*
CROCODILE. Germany, Derbyſhire, Nottinghamſhire, Oxfordſhire, and Yorkſhire, -	
ALLIGATOR'S TEETH. Oxfordſhire, Sheppy iſland, -	*Eaſt and Weſt Indies.*
The BANDED BUCCINUM. Oxfordſhire, and the Alps, -	*Weſt Indies.*
The DIPPING-SNAIL, and STAR-FISH. Sheppy iſland, -	*Weſt Indies.*
TAIL BUCCINUM. Sheppy iſland, Hordel Cliff, Hampſhire, -	*Eaſt Indies.*

Nothing has more perplexed thoſe who undertake to form theories of the earth than theſe appearances. Some have at once boldly aſſerted, from theſe and other phenomena, that the world is eternal. Others have had recourſe to the univerſal deluge. Some, among whom is the Count de Buffon, endeavour to prove that the ocean and dry land are perpetually changing places; that for many ages the higheſt mountains have been covered with water, in conſequence of which the marine animals juſt mentioned were generated in ſuch vaſt quantities, that the waters will again cover theſe mountains. the habitable part of the earth become ſea, and the ſea become dry land as before, &c. Others have imagined that they might be occaſioned by volcanoes, earthquakes, &c. which confound the different ſtrata, and often intermix the productions of the ſea with thoſe of the dry land.

But for a view of the different ſtrata ſo far as they are known; as well as for a view of ſome of the theories which have been propoſed to account for the formation and changes of the earth, ſee GEOLOGY.

Mr Forſter has given an account of ſome of the ſtrata of the South-ſea iſlands, the ſubſtance of which may be ſeen in the following table.

SOUTH GEORGIA.

1. No ſoil, except in a few crevices of the rocks.

Strata.

2. Ponderous ſlate, with ſome irony particles, in horizontal ſtrata, perpendicularly interſected with veins of quartz.

Southern Iſle of New Zealand.

1. Fine light black mould, in ſome places nine inches deep, but generally not ſo much.
2. An argillaceous ſubſtance, nearly related to the claſs of Talcons, turned into earth by the action of the air.
3. The ſame ſubſtance farther indurated, in oblique ſtrata, generally dipping to the ſouth.

Easter Island.

1. Reddiſh-brown duſty mould, looking as if it had been burnt.
2. Burnt rocks, reſembling ſlags or droſs and other volcanic matters.

Marquesas.

1. Clay mixed with mould.
2. An earthy argillaceous ſubſtance mixed with tarras and puzzolana.

Otaheite.

The ſhores are coral rock, extending from the reef encircling theſe iſles to the very high water-mark. There begins the ſand, formed in ſome places from ſmall ſhells and rubbed pieces of coral; but in others the ſhores are covered with blackiſh ſand, conſiſting of the former ſort mixed with black, ſometimes glittering, particles of mica, and here and there ſome particles of the refractory iron ores called in England Skim, the *ferrum micaceum* of Linnæus, and Kall, the *molybdænum ſpuma lupi* of the ſame author. The plains from the ſhores to the foot of the hills are covered with a very fine thick ſtratum of black mould, mixed with the above-mentioned ſand, which the natives manure with ſhells. The firſt and lower range of hills are formed of a red ochreous earth, ſometimes ſo intenſely red, that the natives uſe it to paint their canoes and cloth. The higher hills conſiſt of a hard, compact, and ſtiff clayey ſubſtance, hardening into ſtone when out of the reach of the ſun and air. At the top of the valleys, along the banks of the rivers, are large maſſes of coarſe granite ſtones of various mixtures; in one place are pillars of a grey, ſolid baſaltes; and, in ſeveral others, fragments of black baſaltes.

Friendly Islands and New Hebrides.

The ſame with the above.

Mallicollo.

Yellowiſh clay mixed with common ſand.

Tanna, *a Volcanic Iſland.*

The chief ſtrata here are clay mixed with aluminous earth, interſperſed with lumps of pure chalk. The ſtrata of the clay are about ſix inches, deviating very little from the horizontal line.

New Caledonia and the *adjacent Iſles.*

The ſhores conſiſt of ſhell-ſand, and particles of quartz; the ſoil in the plains a black mould mixed with this ſand. The ſides of the hills compoſed of a yellow ochreous clay, richly ſpangled with ſmall particles of cat-ſilver, or a whitiſh kind of daze, the *mica argentea* of Linnæus. The higher parts of the hills conſiſt of a ſtone called by the German miners *geſtelſtein*, compoſed of quartz and great lumps of the above cat-ſilver. The latter is ſometimes of an intenſely red or orange colour, by means of an iron ochre.

" From the above account, ſays Mr Forſter, it appears, I think, evidently, that all the high tropical iſles of the South ſea have been ſubject to the action of volcanoes. Pyritical and ſulphureous ſubſtances, together with a few iron-ſtones, and ſome veſtiges of copper, are no doubt found in ſeveral of them: but the mountains of New Caledonia are the moſt likely to contain the richeſt metallic veins; and the ſame opinion, I ſuſpect, may be formed of the mountains in New Zealand."

In the city of Modena in Italy, and for ſome miles round that place, there is the moſt ſingular arrangement of ſtrata perhaps in the whole world. From the ſurface of the ground to the depth of 14 feet, they meet with nothing but the ruins of an ancient city. Being come to that depth, they find paved ſtreets, artificers ſhops, floors of houſes, and ſeveral pieces of inlaid work. After theſe ruins they find a very ſolid earth, which one would think had never been removed; but a little lower they find it black and marſhy, and full of briars. Signior Ramazzini in one place found a heap of wheat entire at the depth of 24 feet; in another, he found filbert-trees with their nuts. At the depth of about 28 feet, they find a bed of chalk, about 11 feet deep, which cuts very eaſily; after this a bed of marſhy earth of about two feet, mixed with ruſhes, leaves, and branches. After this bed comes another of chalk, nearly of the ſame thickneſs; and which ends at the depth of 42 feet. This is followed by another bed of marſhy earth like the former; after which comes a new chalk-bed, but thinner, which alſo has a marſhy bed underneath it. This ends at the depth of 63 feet; after which they find ſand mingled with ſmall gravel, and ſeveral marine ſhells. This ſtratum is uſually about five feet deep, and underneath it is a vaſt reſervoir of water. It is on account of this water that the ſoil is ſo frequently dug, and the ſtrata ſo well known in this part of the world. After coming to the ſandy bottom above-mentioned, the workmen pierce the ground with a terebra or augre, when the water immediately ſprings up with great force, and fills the well to the brim. The flow is perpetual, and neither increaſes by rain. nor decreaſes by drought. Sometimes the augre meets with great trees, which give the workmen much trouble; they alſo ſometimes ſee at the bottom of theſe wells great bones, coals, flints, and pieces of iron.

It has been aſſerted by ſome, that the ſpecific gravity of the ſtrata conſtantly increaſed with the depth from the ſurface. But Dr Leigh, in his Natural Hiſtory of Lancaſhire, ſpeaking of the coal-pits, denies the ſtrata to lie according to the laws of gravitation; obſerving, that the ſtrata there are firſt a bed of marle, then free-ſtone, next iron-ſtone, then coal, or channel mire, then ſome other ſtrata, then coal again, &c. This determined Mr Derham to make a nicer inquiry into the matter: accordingly, in 1712, he cauſed divers places to be bored, laying the ſeveral ſtrata by themſelves; and afterwards determined very carefully their ſpecific gravity. The reſult was, that in his yard the ſtrata were gradually ſpecifically heavier and heavier the lower and lower they went; but in another place in his fields, he could not perceive any difference in the ſpecific gravities.

Acquainting the Royal Society therewith, their operator Mr Haukſbee was ordered to try the ſtrata of a coal pit, which he did to the depth of 30 ſtrata: the thickneſs and ſpecific gravity of each whereof he gives us in a table in the Philoſophical Tranſactions; and from the whole makes this inference, that it evidently appears the gravities of the ſeveral ſtrata are in no manner of order, but purely caſual, as if mixed by chance.

Vol. xxvii. p. 541.

STRATAGEM, in the art of war, any device for deceiving and ſurpriſing an enemy. The ancients dealt very much in ſtratagems: the moderns wage war more openly, and on the ſquare. Frontinus has made a collection of the ancient ſtratagems of war.

STRATEGUS, ϛϱατηγος, in antiquity, an officer among the Athenians, whereof there were two choſen yearly, to command the troops of the ſtate.

Plutarch ſays, there was one choſen from out of each tribe; but Pollux ſeems to ſay they were choſen indifferently out of the people. The people themſelves made the choice; and that on the laſt day of the year, in a place called *Pnyx*. The two *ſtrategi* did not command together, but took their turns day by day; as we find from Herodotus and Cornelius Nepos. Sometimes indeed, as when a perſon was found of merit vaſtly ſuperior, and exceedingly famed in war, the command was given to him alone: but it was ever a rule not to put any perſon in the office but whoſe eſtate was in Attica, and who had children, that there might be ſome hoſtages and ſecurities for his conduct and fidelity. Conſtantine the Great, beſides many other privileges granted to the city of Athens, honoured its chief magiſtrate with the title of Μεγας Στρατηγος, *Magnus Dux*.

STRATH, in the Scottiſh language, ſignifies a long narrow valley, with a river running along the bottom.

STRATHEARN, a beautiful and extenſive valley in Perthſhire, bounded on the north by the lofty ridge of mountains called the *Grampians*, and on the ſouth by the Ochils, which are rounded on the tops and covered with verdure. It is called *Strathearn* from the river Earn, which runs through the middle of it from weſt to eaſt for about 30 miles. On each ſide of the banks of this beautiful ſtream are many villages and country-ſeats diſtinguiſhed for romantic ſituations. Were we to ſingle out any of the villages, we would mention Crieff, which ſtands on a fine ſloping ground on the north ſide of the Earn, and has been much admired by travellers for its ſituation, and the variety, contraſt, ſingularity, and beauty of the proſpect which it affords.

STRATHNAVER, a ſubdiviſion or diſtrict of the county of Sutherland in Scotland; bounded on the north by the ocean, on the eaſt by Caithneſs, on the ſouth by Sutherland properly ſo called, and on the weſt partly by Roſs and partly by the ocean.

STRATIOTES, WATER-SOLDIER, a genus of plants belonging to the claſs polyandria. See BOTANY *Index*.

STRATO, a philoſopher of Lampſacus, diſciple and ſucceſſor in the ſchool of Theophraſtus, about 248 years before the Chriſtian era. He applied himſelf with uncommon induſtry to the ſtudy of nature; and after the moſt mature inveſtigations, he ſupported that nature was inanimate, and that there was no god but nature. (See *PLASTIC Nature*). He was appointed preceptor to Ptolemy Philadelphus, who not only revered his abilities and learning, but alſo rewarded his labours with unbounded liberality. He wrote different treatiſes, all now loſt.

STRAWBERRY. See FRAGARIA, BOTANY *Index*.

STRAWBERRY-Tree. See ARBUTUS, BOTANY *Index*.

STRENGTH OF MATERIALS, in *Mechanics*, is a ſubject of ſo much importance, that in a nation ſo eminent as this for invention and ingenuity in all ſpecies of manufactures, and in particular ſo diſtinguiſhed for its improvements in machinery of every kind, it is ſomewhat ſingular that no writer has treated it in the detail which its importance and difficulty demands. The man of ſcience who viſits our great manufactories is delighted with the ingenuity which he obſerves in every part, the innumerable inventions which come even from individual artiſans, and the determined purpoſe of improvement and refinement which he ſees in every workſhop. Every cotton mill appears an academy of mechanical ſcience; and mechanical invention is ſpreading from theſe fountains over the whole kingdom: But the philoſopher is mortified to ſee this ardent ſpirit ſo cramped by ignorance of principle, and many of theſe original and brilliant thoughts obſcured and clogged with needleſs and even hurtful additions, and a complication of machinery which checks improvement even by its appearance of ingenuity. There is nothing in which this want of ſcientific education, this ignorance of principle, is ſo frequently obſerved as in the injudicious proportion of the parts of machines and other mechanical ſtructures; proportions and forms of parts in which the ſtrength and poſition are nowiſe regulated by the ſtrains to which they are expoſed, and where repeated failures have been the only leſſons.

1 Importance of the ſubject.

It cannot be otherwiſe. We have no means of inſtruction, except two very ſhort and abſtracted treatiſes of the late Mr Emerſon on the ſtrength of materials. We do not recollect a performance in our language from which our artiſts can get information. Treatiſes written expreſsly on different branches of mechanical arts are totally ſilent on this, which is the baſis and *only principle* of their performances. Who would imagine that PRICE'S BRITISH CARPENTER, the work of the firſt reputation in this country, and of which the ſole aim is to teach the carpenter to erect ſolid and durable ſtructures, does not contain one propoſition or one reaſon by which one form of a thing can be ſhown to be ſtronger or weaker than another? We doubt very much if one carpenter in an hundred can give a reaſon to convince his own mind that a joiſt is ſtronger when laid on its edge than when laid on its broad ſide. We ſpeak in this ſtrong manner in hopes of exciting ſome man of ſcience to publiſh a ſyſtem of inſtruction on this ſubject. The limits of our Work will not admit of a detail: but we think it neceſſary to point out the leading principles, and to give the traces of that ſyſtematic connection by which all the knowledge already poſſeſſed of this ſubject may be brought

brought together and properly arranged. This we ſhall now attempt in as brief a manner as we are able.

2 Strength of materials ariſes from coheſion.

THE ſtrength of materials ariſes immediately or ultimately from the coheſion of the parts of bodies. Our examination of this property of tangible matter has as yet been very partial and imperfect, and by no means enables us to apply mathematical calculations with preciſion and ſucceſs. The various modifications of coheſion, in its different appearances of perfect ſoftneſs, plaſticity, ductility, elaſticity, hardneſs, have a mighty influence on the ſtrength of bodies, but are hardly ſuſceptible of meaſurement. Their texture alſo, whether uniform like glaſs and ductile metals, cryſtallized or granulated like other metals and freeſtone, or fibrous like timber, is a circumſtance no leſs important; yet even here, although we derive ſome advantage from remarking to which of theſe forms of aggregation a ſubſtance belongs, the aid is but ſmall. All we can do in this want of general principles is to make experiments on every claſs of bodies. Accordingly philoſophers have endeavoured to inſtruct the public in this particular. The Royal Society of London at its very firſt inſtitution made many experiments at their meetings, as may be ſeen in the firſt regiſters of the Society *. Several individuals have added their experiments. The moſt numerous collection in detail is by Muſchenbroek, profeſſor of natural philoſophy at Leyden. Part of it was publiſhed by himſelf in his *Eſſais de Phyſique*, in two vols. 4to; but the full collection is to be found in his Syſtem of Natural Philoſophy, publiſhed after his death by Lulofs, in three vols 4to. This was tranſlated from the Low Dutch into French by Sigaud de la Fond, and publiſhed at Paris in 1760, and is a prodigious collection of phyſical knowledge of all kinds, and may almoſt ſuffice for a library of natural philoſophy. But this collection of experiments on the coheſion of bodies is not of that value which one expects. We preſume that they were carefully made and faithfully narrated; but they were made on ſuch ſmall ſpecimens, that the unavoidable natural inequalities of growth or texture produced irregularities in the reſults which bore too great a proportion to the whole quantities obſerved. We may make the ſame remark on the experiments of Couplet, Pitot, De la Hire, Du Hamel, and others of the French academy. In ſhort, if we except the experiments of Buffon on the ſtrength of timber, made at the public expence on a large ſcale, there is nothing to be met with from which we can obtain abſolute meaſures which may be employed with confidence; and there is nothing in the Engliſh language except a ſimple liſt by Emerſon, which is merely a ſet of affirmations, without any narration of circumſtances, to enable us to judge of the validity of his concluſions: but the character of Mr Emerſon, as a man of knowledge and of integrity, gives even to theſe aſſertions a conſiderable value.

3 Experiments to aſcertain it.

* See Birche's *Hiſtory*, and Hooke's *Mathematical Collections*.

4 Rendered uſeful by generalization.

But to make uſe of any experiments, there muſt be employed ſome general principle by which we can generalize their reſults. They will otherwiſe be only narrations of detached facts. We muſt have ſome notion of that intermedium, by the intervention of which an external force applied to one part of a lever, joiſt, or pillar, occaſions a ſtrain on a diſtant part. This can be nothing but the coheſion between the parts. It is this connecting force which is brought into action, or, as we more ſhortly expreſs it, excited. This action is modified in every part by the laws of mechanics. It is this action which is what we call the *ſtrength* of that part, and its effect is the ſtrain on the adjoining parts; and thus it is the ſame force, differently viewed, that conſtitutes both the ſtrain and the ſtrength. When we conſider it in the light of a reſiſtance to fracture, we call it *ſtrength*.

5 Strength defined.

We call every thing a *force* which we obſerve to be ever accompanied by a change of motion; or, more ſtrictly ſpeaking, we infer the preſence and agency of a force wherever we obſerve the ſtate of things in reſpect of motion different from what we know to be the reſult of the action of all the forces which we know to act on the body. Thus when we obſerve a rope prevent a body from falling, we infer a moving force inherent in the rope with as much confidence as when we obſerve it drag the body along the ground. The *immediate action* of this force is undoubtedly exerted between the immediately adjoining parts of the rope. The immediate effect is the keeping the particles of the rope together. They ought to ſeparate by any external force drawing the ends of the rope contrarywiſe; and we aſcribe their not doing ſo to a mechanical force really oppoſing this external force. When deſired to give it a name, we name it from what we conceive to be its effect, and therefore its characteriſtic, and we call it COHESION. This is merely a name for the fact; but it is the ſame thing in all our denominations. We know nothing of the cauſes but in the effects; and our name for the cauſe is in fact the name of the effect, which is COHESION. We mean nothing elſe by gravitation or magnetiſm. What do we mean when we ſay that Newton underſtood thoroughly the nature of gravitation, of the force of gravitation; or that Franklin underſtood the nature of the electric force? Nothing but this: Newton conſidered with patient ſagacity the general facts of gravitation, and has deſcribed and claſſed them with the utmoſt preciſion. In like manner, we ſhall underſtand the nature of coheſion when we have diſcovered with equal generality the laws of coheſion, or general facts which are obſerved in the appearances, and when we have deſcribed and claſſed them with equal accuracy.

6 Cauſes known only from their effects.

Let us therefore attend to the more ſimple and obvious phenomena of coheſion, and mark with care every circumſtance of reſemblance by which they may be claſſed. Let us receive theſe as the laws of coheſion, characteriſtic of its ſuppoſed cauſe, the force of coheſion. We cannot pretend to enter on this vaſt reſearch. The modifications are innumerable: and it would require the penetration of more than Newton to detect the circumſtance of ſimilarity amidſt millions of diſcriminating circumſtances. Yet this is the only way of diſcovering which are the primary facts characteriſtic of the force, and which are the modifications. The ſtudy is immenſe, but it is by no means deſperate; and we entertain great hopes that it will ere long be ſucceſsfully proſecuted: but, in our particular predicament, we muſt content ourſelves with ſelecting ſuch general laws as ſeem to give us the moſt immediate information of the circumſtances that muſt be attended to by the mechanician in his conſtructions, that he may unite ſtrength with ſimplicity, economy, and energy.

1. Then, it is a matter of fact that all bodies are in a

certain degree perfectly elaftic; that is, when their form or bulk is changed by certain moderate compreffions or diftractions, it requires the continuance of the changing force to continue the body in this new ftate; and when the force is removed, the body recovers its original form. We limit the affertion to *certain moderate* changes: For inftance, take a lead wire of one-fifteenth of an inch in diameter and ten feet long; fix one end firmly to the ceiling, and let the wire hang perpendicular; affix to the lower end an index like the hand of a watch; on fome ftand immediately below let there be a circle divided into degrees, with its centre correfponding to the lower point of the wire: now turn this index twice round, and thus twift the wire. When the index is let go, it will turn backwards again, by the wire's untwifting itfelf, and make almoft four revolutions before it ftops; after which it twifts and untwifts many times, the index going backwards and forwards round the circle, diminifhing however its arch of twift each time, till at laft it fettles precifely in its original pofition. This may be repeated for ever. Now, in this motion, every part of the wire partakes equally of the twift. The particles are ftretched, require force to keep them in their ftate of extenfion, and recover completely their relative pofitions. Thefe are all the characters of what the mechanician calls *perfect* elafticity. This is a quality quite familiar in many cafes; as in glafs, tempered fteel, &c. but was thought incompetent to lead, which is generally confidered as having little or no elafticity. But we make the affertion in the moft general terms, with the limitation to moderate derangement of form. We have made the fame experiment on a thread of pipe-clay, made by forcing foft clay through the fmall hole of a fyringe by means of a fcrew; and we found it more elaftic than the lead wire: for a thread of one-twentieth of an inch diameter and feven feet long allowed the index to make two turns, and yet completely recovered its firft pofition.

7 All bodies elaftic.

2. But if we turn the index of the lead wire four times round, and let it go again, it untwifts again in the fame manner, but it makes little more than four turns back again; and after many ofcillations it finally ftops in a pofition almoft two revolutions removed from its original pofition. It has now acquired a new arrangement of parts, and this new arrangement is permanent like the former; and, what is of particular moment, it is perfectly elaftic. This change is familiarly known by the denomination of a SET. The wire is faid to have TAKEN A SET. When we attend minutely to the procedure of nature in this phenomenon, we find that the particles have as it were flid on each other, ftill cohering, and have taken a new pofition, in which their connecting forces are in equilibrio: and in this change of relative fituation, it appears that the connecting forces which maintained the particles in their firft fituation were not in equilibrio in fome pofition intermediate between that of the firft and that of the laft form. The force required for changing this firft form augmented with the change, but only to a certain degree; and during this procefs the connecting forces always tended to the recovery of this firft form. But after the change of mutual pofition has paffed a certain magnitude, the union has been partly deftroyed, and the particles have been brought into new fituations; fuch, that the forces which now connect each with its neighbour tend, not to the recovery of the firft arrangement, but to pufh them farther from it, into a new fituation, to which they now verge, and require force to prevent them from acquiring. The wire is now in fact again perfectly elaftic; that is, the forces which now connect the particles with their neighbours augment to a certain degree as the derangement from this new pofition augments. This is not reafoning from any theory. It is narrating facts, on which a theory is to be founded. What we have been juft now faying is evidently a defcription of that fenfible form of tangible matter which we call *ductility*. It has every gradation of variety, from the foftnefs of butter to the firmnefs of gold. All thefe bodies have fome elafticity; but we fay they are not perfectly elaftic, becaufe they do not completely recover their original form when it has been greatly damaged. The whole gradation may be moft diftinctly obferved in a piece of glafs or hard fealing wax. In the ordinary form glafs is perhaps the moft completely elaftic body that we know, and may be bent till juft ready to fnap, and yet completely recovers its firft form, and takes no fet whatever; but when heated to fuch a degree as juft to be vifible in the dark, it lofes its brittlenefs, and becomes fo tough that it cannot be broken by any blow; but it is no longer elaftic, takes any fet, and keeps it. When more heated, it becomes as plaftic as clay; but in this ftate is remarkably diftinguifhed from clay by a quality which we may call VISCIDITY, which is fomething like elafticity, of which clay and other bodies purely plaftic exhibit no appearance. This is the joint operation of ftrong adhefion and foftnefs. When a rod of perfectly foft glafs is fuddenly ftretched a little, it does not at once take the fhape which it acquires after fome little time. It is owing to this, that in taking the impreffion of a feal, if we take off the feal while the wax is yet very hot, the fharpnefs of the impreffion is deftroyed immediately. Each part drawing its neighbour, and each part yielding, the prominent parts are pulled down and blunted, and the fharp hollows are pulled upwards and alfo blunted. The feal muft be kept on till all has become not only ftiff but hard.

8 What is meant by a *fet*.

9 Ductility.

10 Vifcidity.

This vifcidity is to be obferved in all plaftic bodies which are homogeneous. It is not obferved in clay, becaufe it is not homogeneous, but confifts of hard particles of argillaceous earth fticking together by their attraction for water. Something like it might be made of finely powdered glafs and a clammy fluid fuch as turpentine. Vifcidity has all degrees of foftnefs till it degenerates to ropy fluidity like that of olive oil. Perhaps fomething of it may be found even in the moft perfect fluid that we are acquainted with, as we obferved in the experiments for afcertaining fpecific gravity.

11 Obferved in all homogeneous plaftic bodies.

There is in a late volume of the Philofophical Tranfactions a narrative of experiments, by which it appears that the thread of the fpider is an exception to our firft general law, and that it is perfectly ductile. It is there afferted, that a long thread of goffamer, furnifhed with an index, takes any pofition whatever; and that though the index be turned round any number of times (even many hundreds), it has no tendency to recover its firft form. The thread takes completely any fet whatever. We have not had an opportunity of repeating this experiment, but we have diftinctly obferved a phenomenon totally inconfiftent with it. If a fibre of goffamer about an inch long be held by the end horizontally, it bends downward

downward in a curve like a ſlender ſlip of whalebone or a hair. If totally devoid of elaſticity, and perfectly indifferent to any ſet, it would hang down perpendicularly without any curvature.

When ductility and elaſticity are combined in different proportions, an immenſe variety of ſenſible modes of aggregation may be produced. Some degree of both are probably to be obſerved in all bodies of complex conſtitution; that is, which conſiſt of particles made up of many different kinds of atoms. Such a conſtitution of a body muſt afford many ſituations permanent, but eaſily deranged.

In all theſe changes of diſpoſition which take place among the particles of a ductile body, the particles are at ſuch diſtance that they ſtill cohere. The body may be ſtretched a little; and on removing the extending force, the body ſhrinks into its firſt form. It alſo re-
12 Particles acted on by attractions and repulſions
ſiſts moderate compreſſions; and when the compreſſing force is removed, the body ſwells out again. Now the corpuſcular *fact* here is, that the particles are acted on by attractions and repulſions, which balance each other when no external force is acting on the body, and which augment as the particles are made, by any external cauſe, to recede from this ſituation of mutual inactivity; for ſince force is requiſite to produce either the dilatation or the compreſſion, and to maintain it, we are obliged, by the conſtitution of our minds, to infer that it is oppoſed by a force accompanying or inherent in every particle of dilatable or compreſſible matter; and as this neceſſity of employing force to produce a change indicates the agency of theſe corpuſcular forces, and marks their kind, according as the tendencies of the particles appear to be toward each other in dilatation, or from each other in compreſſion; ſo it alſo meaſures the degrees of their intenſity. Should it require three times the force to produce a double compreſſion, we muſt reckon the mutual repulſions triple when the compreſſion is doubled; and ſo in other inſtances. We ſee from all
13 The great problem in corpuſcular mechaniſm.
this that the phenomena of coheſion indicate ſome relation between the centres of the particles. To diſcover this relation is the great problem in corpuſcular mechaniſm, as it was in the Newtonian inveſtigation of the force of gravitation. Could we diſcover this law of action between the corpuſcles with the ſame certainty and diſtinctneſs, we might with equal confidence ſay what will be the reſult of any poſition which we give to the particles of bodies; but this is beyond our hopes. The law of gravitation is ſo ſimple, that the diſcovery or detection of it amid the variety of celeſtial phenomena required but one ſtep; and in its own nature its poſſible combinations ſtill do not greatly exceed the powers of human reſearch. One is almoſt diſpoſed to ſay that the Supreme Being has exhibited it to our reaſoning powers as ſufficient to employ with ſucceſs our utmoſt efforts, but not ſo abſtruſe as to diſcourage us from the noble attempt. It ſeems to be otherwiſe with reſpect to coheſion. Mathematics informs us, that if it deviates ſenſibly from the law of gravitation, the ſimpleſt combinations will make the joint action of ſeveral particles an almoſt impenetrable myſtery. We muſt therefore content ourſelves, for a long time to come, with a careful obſervation of the ſimpleſt caſes that we can propoſe, and with the diſcovery of ſecondary laws of action, in which many particles combine their influence. In purſuance of this plan, we obſerve,

3. That whatever is the ſituation of the particles of a body with reſpect to each other, when in a quieſcent ſtate, they are kept in theſe ſituations by the balance of oppoſite forces. This cannot be refuſed, nor can we
14 Particles kept in their places by a balance of forces.
form to ourſelves any other notion of the ſtate of the particles of a body. Whether we ſuppoſe the ultimate particles to be of certain magnitudes and ſhapes, touching each other in ſingle points of coheſion; or whether we (with Boſcovich) conſider them as at a diſtance from each other, and acting on each other by attractions and repulſions—we muſt acknowledge, in the firſt place, that the centres of the particles (by whoſe mutual diſtances we muſt eſtimate the diſtance of the particles) may and do vary their diſtances from each other. What elſe can we ſay when we obſerve a body increaſe in length, in breadth, and in thickneſs, by heating it, or when we ſee it diminiſh in all theſe dimenſions by an external compreſſion? A particle, therefore, ſituated in the midſt of many others, and remaining in that ſituation, muſt be conceived as maintained in it by the mutual balancing of all the forces which connect it with its neighbours. It is like a ball kept in its place by the
15 Illuſtration of this propoſition.
oppoſite action of two ſprings. This illuſtration merits a more particular application. Suppoſe a number of balls ranged on the table in the angles of equilateral triangles, and that each ball is connected with the ſix which lie around it by means of an elaſtic wire curled like a cork-ſcrew; ſuppoſe ſuch another ſtratum of balls above this, and parallel to it, and ſo placed that each ball of the upper ſtratum is perpendicularly over the centre of the equilateral triangle below, and let theſe be connected with the balls of the under ſtratum by ſimilar ſpiral wires. Let there be a third and a fourth, and any number of ſuch ſtrata, all connected in the ſame manner. It is plain that this may extend to any ſize and fill any ſpace.—Now let this aſſemblage of balls be firmly contemplated by the imagination, and be ſuppoſed to ſhrink continually in all its dimenſions, till the balls, and their diſtances from each other, and the connecting wires, all vaniſh from the ſight as diſcrete individual objects. All this is very conceivable. It will now appear like a ſolid body, having length, breadth, and thickneſs; it may be compreſſed, and will again reſume its dimenſions; it may be ſtretched, and will again ſhrink; it will move away when ſtruck; in ſhort, it will not differ in its ſenſible appearance from a ſolid elaſtic body. Now when this body is in a ſtate of compreſſion, for inſtance, it is evident that any one of the balls is at reſt, in conſequence of the mutual balancing of the actions of all the ſpiral wires which connect it with thoſe around it. It will greatly conduce to the full underſtanding of all that follows to recur to this illuſtration. The analogy or reſemblance between the effects of this conſtitution of things and the effects of the corpuſcular forces is very great; and wherever it obtains, we may ſafely draw concluſions from what we know would be the condition of a body of common tangible matter. We ſhall juſt give
16 By example.
one inſtructive example, and then have done with this hypothetical body. We can ſuppoſe it of a long ſhape, reſting on one point; we can ſuppoſe two weights A, B, ſuſpended at the extremities, and the whole in equilibrio. We commonly expreſs this ſtate of things by ſaying that A and B are in equilibrio. This is very inaccurate. A is in fact in equilibrio with the united action of all the ſprings which connect the ball to which it is applied with

Strength of Materials.

with the adjoining balls. Theſe ſprings are brought into action, and each is in equilibrio with the joint action of all the reſt. Thus through the whole extent of the hypothetical body, the ſprings are brought into action in a way and in a degree which mathematics can eaſily inveſtigate. We need not do this: it is enough for our purpoſe that our imagination readily diſcovers that ſome ſprings are ſtretched, others are compreſſed, and that a preſſure is excited on the middle point of ſupport, and the ſupport exerts a reaction which preciſely balances it; and the other weight is, in like manner, in immediate equilibrio with the equivalent of the actions of all the ſprings which connect the laſt ball with its neighbours. Now take the analogical or reſembling caſe, an oblong piece of ſolid matter, reſting on a fulcrum, and loaded with two weights in equilibrio. For the actions of the connecting ſprings ſubſtitute the corpuſcular forces, and the reſult will reſemble that of the hypotheſis.

Now as there is ſomething that is at leaſt analogous to a change of diſtance of the particles, and a concomitant change of the intenſity of the connecting forces, we may expreſs this in the ſame way that we are accuſtomed to do in ſimilar caſes. Let A and B (fig. 1.) repreſent the centres of two particles of a coherent elaſtic body in their quieſcent inactive ſtate, and let us conſider only the mechanical condition of B. The body may be ſtretched. In this caſe the diſtance A B of the particles may become A C. In this ſtate there is ſomething which makes it neceſſary to employ a force to keep the particles at this diſtance. C has a tendency towards A, or we may ſay that A attracts C. We may repreſent the magnitude of this tendency of C *towards* A, or this attraction of A, by a line C *c* perpendicular to A C. Again, the body may be compreſſed, and the diſtance A B may become A D. Something obliges us to employ force to continue this compreſſion; and D tends *from* A, or A appears to *repel* D. The intenſity of this tendency or repulſion may be repreſented by another perpendicular D *d*; and, to repreſent the different directions of theſe tendencies, or the different nature of theſe actions, we may ſet D *d* on the oppoſite ſide of A B. It is in this manner that the Abbé Boſcovich has repreſented the actions of corpuſcular forces in his celebrated Theory of Natural Philoſophy. Newton had ſaid, that, as the great movements of the ſolar ſyſtem were regulated by forces operating at a diſtance, and varying with the diſtance, ſo he ſtrongly ſuſpected (*valde ſuſpicor*) that all the phenomena of coheſion, with all its modifications in the different ſenſible forms of aggregation, and in the phenomena of chemiſtry and phyſiology, reſulted from the ſimilar agency of forces varying with the diſtance of the particles. The learned Jeſuit purſued this thought; and has ſhown, that if we ſuppoſe an ultimate atom of matter endowed with powers of attraction and repulſion, varying, both in kind and degree, with the diſtance, and if this force be the ſame in every atom, it may be regulated by ſuch a relation to the diſtance from the neighbouring atom, that a collection of ſuch may have all the ſenſible appearance of bodies in their different forms of ſolids, liquids, and vapours, elaſtic or unelaſtic, and endowed with all the properties which we perceive, by whoſe immediate operation the phenomena of motion by impulſe, and all the phenomena of chemiſtry, and of animal and vegetable economy, may be produced. He ſhows, that notwithſtanding a perfect ſameneſs, and even a great ſimplicity in this atomical conſtitution, there will reſult from this union all that unſpeakable variety of form and property which diverſify and embelliſh the face of nature. We ſhall take another opportunity of giving ſuch an account of this celebrated work as it deſerves. We mention it only, by the bye, as far as a general notion of it will be of ſome ſervice on the preſent occaſion. For this purpoſe, we juſt obſerve that Boſcovich conceives a particle of any individual ſpecies of matter to conſiſt of an unknown number of particles of ſimpler conſtitution; each of which particles, in their turn, is compounded of particles ſtill more ſimply conſtituted, and ſo on through an unknown number of orders, till we arrive at the ſimpleſt poſſible conſtitution of a particle of tangible matter, ſuſceptible of length, breadth, and thickneſs, and neceſſarily conſiſting of four atoms of matter. And he ſhows that the more complex we ſuppoſe the conſtitution of a particle, the more muſt the ſenſible qualities of the aggregate reſemble the obſerved qualities of tangible bodies. In particular, he ſhows how a particle may be ſo conſtituted, that although it act on one other particle of the ſame kind through a conſiderable interval, the interpoſition of a third particle of the ſame kind may render it totally, or almoſt totally, inactive; and therefore an aſſemblage of ſuch particles would form ſuch a fluid as air. All theſe curious inferences are made with uncontrovertible evidence; and the greateſt encouragement is thus given to the mathematical philoſopher to hope, that by cautious and patient proceeding in this way, we may gradually approach to a knowledge of the laws of coheſion, that will not ſhun a compariſon even with the *Principia* of Newton. No ſtep can be made in this inveſtigation, but by obſerving with care, and generalizing with judgement, the phenomena, which are abundantly numerous, and much more at our command than thoſe of the great and ſenſible motions of bodies. Following this plan, we obſerve, 18

Plate DXI. Fig. 1.

17 How Boſcovich repreſents the action of corpuſcular forces.

Every body compreſſible and dilatable.

4. It is matter of fact, that every body has ſome degree of compreſſibility and dilatability; and when the changes of dimenſion are ſo moderate that the body completely recovers its original dimenſions on the ceſſation of the changing force, the extenſions or compreſſions are ſenſibly proportional to the extending or compreſſing forces: and therefore *the connecting forces are proportional to the diſtances of the particles from their quieſcent, neutral, or inactive poſitions*. This ſeems to have been firſt viewed as a law of nature by the penetrating eye of Dr Robert Hooke, one of the moſt eminent philoſophers of the laſt century. He publiſhed a cipher, which he ſaid contained the theory of ſpringineſs and of the motions of bodies by the action of ſprings. It was this, *c e i i i n o s s s t t u u*.—When explained in his diſſertation, publiſhed ſome years after, it was *ut tenſio ſic vis*. This is preciſely the propoſition juſt now aſſerted as a general fact, a law of nature. This diſſertation is full of curious obſervations of facts in ſupport of his aſſertion. In his application to the motion of bodies he gives his noble diſcovery of the balance-ſpring of a watch, which is founded on this law. The ſpring, as it is more and more coiled up, or unwound, by the motion of the balance, acts on it with a force proportional to the diſtance of the balance from its quieſcent poſition. The balance therefore is acted on by an accelerating force, which varies in the ſame manner as the force of gravity

19 Law of nature diſcovered by Dr Hooke.

gravity acting on a pendulum ſwinging in a cycloid. Its vibrations therefore muſt be performed in equal time, whether they are wide or narrow. In the ſame diſſertation Hooke mentions all the facts which John Bernoulli afterwards adduced in ſupport of Leibnitz's whimſical doctrine of the force of bodies in motion, or the doctrine of the *vires vivæ;* a doctrine which Hooke might juſtly have claimed as his own, had he not ſeen its futility.

20
And confirmed by the experiments of others.

Experiments made ſince the time of Hooke ſhow that this law is ſtrictly true in the extent to which we have limited it, viz. in all the changes of form which will be completely undone by the elaſticity of the body. It is nearly true to a much greater extent. James Bernoulli, in his diſſertation on the elaſtic curve, relates ſome experiments of his own, which ſeem to deviate conſiderably from it; but on cloſe examination they do not. The fineſt experiments are thoſe of Coulomb, publiſhed in ſome late volumes of the memoirs of the Academy of Paris. He ſuſpended balls by wires, and obſerved their motions of oſcillation, which he found accurately correſponding with this law.

This we ſhall find to be a very important fact in the doctrine of the ſtrength of bodies, and we deſire the reader to make it familiar to his mind. If we apply to this our manner of expreſſing theſe forces by perpendicular ordinates Cc, Dd (fig. 1.), we muſt take other ſituations E, F, of the particle B, and draw Ee, Ff; and we muſt have $Dd : Ff = BD : BF$, or $Cc : Ee = BC : BE$. In ſuch a ſuppoſition $FdBce$ muſt be a ſtraight line. But we ſhall have abundant evidence by and bye that this cannot be ſtrictly true, and that the line Bce which limits the ordinates expreſſing the attractive forces becomes concave towards the line ABE, and that the part Bdf is convex towards it. All that can be ſafely concluded from the experiments hitherto made is, that *to a certain extent* the forces, both attractive and repulſive, are *ſenſibly* proportional to the dilatations and compreſſions. For,

21
When a body is much dilated, a ſmall addition of force will increaſe its dilatation.

5. It is univerſally obſerved, that when the dilatations have proceeded a certain length, a leſs addition of force is ſufficient to increaſe the dilatation in the ſame degree. This is always obſerved when the body has been ſo far ſtretched that it takes a ſet, and does not completely recover its form. The like may be generally obſerved in compreſſions. Moſt perſons will recollect, that in violently ſtretching an elaſtic cord, it becomes ſuddenly weaker, or more eaſily ſtretched. But theſe phenomena do not poſitively prove a diminution of the corpuſcular force acting on one particle: It more probably ariſes from the diſunion of ſome particles, whoſe action contributed to the whole or ſenſible effect. And in compreſſions we may ſuppoſe ſomething of the ſame kind; for when we compreſs a body in one direction, it commonly bulges out in another; and in caſes of very violent action ſome particles may be diſunited, whoſe tranſverſe action had formerly balanced *part* of the compreſſing force. For the reader will ſee on reflection, that ſince the compreſſion in one direction cauſes the body to bulge out in the tranſverſe direction; and ſince this bulging out is in oppoſition to the tranſverſe forces of attraction, it muſt employ ſome part of the compreſſing force. And the common appearances are in perfect uniformity with this conception of things. When we preſs a bit of dryiſh clay, it ſwells out and cracks tranſverſely. When a pillar of wood is overloaded, it ſwells out, and ſmall crevices appear in the direction of the fibres. After this it will not bear half of the load. This the carpenters call CRIPPLING; and a knowledge of the circumſtances which modify it is of great importance, and enables us to underſtand ſome very paradoxical appearances, as will be ſhown by and bye.

This partial diſuniting of particles formerly cohering is, we imagine, the chief reaſon why the totality of the forces which really oppoſe an external ſtrain does not increaſe in the proportion of the extenſions and compreſſions. But ſufficient evidence will alſo be given that the forces which would connect one particle with one other particle do not augment in the accurate proportion of the change of diſtance; that in extenſions they increaſe more ſlowly, and in compreſſions more rapidly.

22
Ductility another cauſe of deviation.

But there is another cauſe of this deviation perhaps equally effectual with the former. Moſt bodies manifeſt ſome degree of ductility. Now what is this? The fact is, that the parts have taken a new arrangement, in which they again cohere. Therefore, in the paſſage to this new arrangement, the ſenſible forces, which are the joint reſult of many corpuſcular forces, begin to reſpect this new arrangement inſtead of the former. This muſt change the ſimple law of corpuſcular force, characteriſtic of the particular ſpecies of matter under examination. It does not require much reflection to convince us that the poſſible arrangements which the particles of a body may acquire, without appearing to change their nature, muſt be more numerous according as the particles are of a more complex conſtitution; and it is reaſonable to ſuppoſe that the conſtitution even of the moſt ſimple kind of matter that we are acquainted with is exceedingly complex. Our microſcopes ſhow us animals ſo minute, that a heap of them muſt appear to the naked eye an uniform maſs with a grain finer than that of the fineſt marble or razor hone; and yet each of theſe has not only limbs, but bones, muſcular fibres, blood-veſſels, fibres, and a blood conſiſting, in all probability, of globules organiſed and complex like our own. The imagination is here loſt in wonder; and nothing is left us but to adore inconceivable art and wiſdom, and to exult in the thought that we are the only ſpectators of this beautiful ſcene who can derive pleaſure from the view. What is trodden under foot with indifference, even by the half-reaſoning elephant, may be made by us the ſource of the pureſt and moſt unmixed pleaſure. But let us proceed to obſerve,

23
The forces which connect the particles of tangible bodies change by a change of diſtance.

6. That the forces which connect the particles of tangible bodies change by a change of diſtance, not only in degree, but alſo in kind. The particle B (fig. 1.) is attracted by A when in the ſituation C or E. It is repelled by it when at D or F. It is not affected by it when in the ſituation B. The reader is requeſted carefully to remark, that this is not an inference founded on the authority of our mathematical figure. The figure is an expreſſion (to aſſiſt the imagination) of facts in nature. It requires no force to keep the particles of a body in their quieſcent ſituations: but if they are ſeparated by ſtretching the body, they endeavour (pardon the figurative expreſſion) to come together again. If they are brought nearer by compreſſion, they endeavour to recede. This endeavour is manifeſted by the neceſſity of employing force to maintain the extenſion or condenſation; and we repreſent this by the different poſition of

Strength of Materials.

of our lines. But this is not all: the particle B, which is repelled by A when in the situation F or D, is neutral when at B, and is attracted when at C or E, may be placed at such a distance AG from A greater than AB that it shall be again repelled, or at such a distance AH that it shall again be attracted; and these alterations may be repeated again and again. This is curious and important, and requires something more than a bare assertion for its proof.

24
Light alternately attracted and repelled.

In the article OPTICS we mentioned the most curious and valuable observations of Sir Isaac Newton, by which it appears that light is thus alternately attracted and repelled by bodies. The rings of colour which appear between the object glasses of long telescopes showed, that in the small interval of $\frac{1}{1000}$th of an inch, there are at least an hundred such changes observable, and that it is highly probable that these alternations extend to a much greater distance. At one of these distances the light actually converges towards the solid matter of the glass, which we express shortly, by saying that it is attracted by it, and that at the next distance it declines from the glass, or is repelled by it. The same thing is more simply inferred from the phenomena of light passing by the edges of knives and other opaque bodies. We refer the reader to the experiments themselves, the detail being too long for this place; and we request him to consider them minutely and attentively, and to form distinct notions of the inferences drawn from them. And we desire it to be remarked, that although Sir Isaac, in his discussion, always considers light as a set of corpuscles moving in free space, and obeying the actions of external forces like any other matter, the particular conclusion in which we are just now interested does not at all depend on this notion of the nature of light. Should we, with Des Cartes or Huygens, suppose light to be the undulation of an elastic medium, the conclusion will be the same. The undulations at certain distances are disturbed by forces directed towards the body, and at a greater distance, the disturbing forces tend *from* the body.

25
The same alternations of attraction and repulsion observable in the particles of other bodies, as glass.

But the same alternations of attraction and repulsion may be observed between the particles of common matter. If we take a piece of very flat and well-polished glass, such as is made for the horizon glasses of a good Hadley's quadrant, and if we wrap round it a fibre of silk as it comes from the cocoon, taking care that the fibre nowhere cross another, and then press this pretty hard on such another piece of glass, it will lift it up and keep it suspended. The particles therefore of the one do most certainly attract those of the other, and this at a distance equal to the thickness of the silk fibre. This is nearly the limit; and it sometimes requires a considerable pressure to produce the effect. The pressure is effectual only by compressing the silk fibre, and thus diminishing the distance between the glass plates. This adhesion cannot be attributed to the pressure of the atmosphere, because there is nothing to hinder the air from insinuating itself between the plates, since they are separated by the silk. Besides, the experiment succeeds equally well under the receiver of an air-pump. This most valuable experiment was first made by Huygens, who reported it to the Royal Society. It is narrated in the Philosophical Transactions, N° 86.

Here then is an attraction acting, like gravity, at a distance. But take away the silk fibre, and try to make the glasses touch each other, and we shall find a very great force necessary. By Newton's experiments it appears, that unless the prismatic colours begin to appear between the glasses, they are at least $\frac{1}{890}$th of an inch asunder or more. Now we know that a very considerable force is necessary for producing these colours, and that the more we press the glasses together the more rings of colours appear. It also appears from Newton's measures, that the difference of distance between the glasses where each of these colours appear is about the 89,000th part of an inch. We know farther, that when we have produced the last appearance of a greasy or pearly colour, and then augment the pressure, making it about a thousand pounds on the square inch, all colours vanish, and the two pieces of glass seem to make one transparent undistinguishable mass. They appear now to have no air between them, or to be in mathematical contact. But another fact shows this conclusion to be premature. The same circles of colours appear in the top of a soap bubble; and as it grows thinner at top, there appears an unreflecting spot in the middle. We have the greatest probability therefore that the perfect transparency in the middle of the two glasses does not arise from their being in contact, but because the thickness of air between them is too small in that place for the reflection of light. Nay, Newton expressly found no reflection where the thickness was $\frac{2}{5}$ths or more of the $\frac{1}{89000}$th part of an inch.

All this while the glasses are strongly repelling each other, for great pressure is necessary for continuing the appearance of those colours, and they vanish in succession as the pressure is diminished. This vanishing of the colours is a proof that the glasses are moving off from each other, or repelling each other. But we can put an end to this repulsion by very strong pressure, and at the same time sliding the glasses on each other. We do not pretend to account for this effect of the sliding motion; but the fact is, that by so doing, the glasses will cohere with very great force, so that we shall break them by any attempt to pull them asunder. It commonly happens (at least it did so with us), that in this sliding compression of two smooth flat plates of glass they scratch and mutually destroy each other's surface. It is also worth remarking, that different kinds of glass exhibit different properties in this respect. Flint glass will attract even though a silk fibre lies double between them, and they much more readily cohere by this sliding pressure.

Here then are two distances at which the plates of glass attract each other; namely, when the silk fibre is interposed, and when they are forced together with this sliding motion. And in any intermediate situation they repel each other. We see the same thing in other solid bodies. Two pieces of lead made perfectly clean, may be made to cohere by grinding them together in the same manner. It is in this way that pretty ornaments of silver are united to iron. The piece is scraped clean, and a small bit of silver like a fish scale is laid on. The die which is to strike it into a flower or other ornament is then set on it, and we give it a smart blow, which forces the metals into contact as firm as if they were soldered together. It sometimes happens that the die adheres to the coin so that they cannot be separated: and it is found that this frequently happens, when the engraving is such, that the raised figure is not complete-

26
Lead and iron.

ly

ly ſurrounded with a ſmooth flat ground. The probable cauſe of this is curious. When the coin has a flat ſurface all around, this is produced by the moſt prominent part of the die. This applies to the metal, and completely confines the air which filled the hollow of the die. As the preſſure goes on, the metal is ſqueezed up into the hollow of the die; but there is ſtill air compreſſed between them, which cannot eſcape by any paſſage. It is therefore prodigiouſly condenſed, and exerts an elaſticity proportioned to the condenſation. This ſerves to ſeparate the die from the metal when the ſtroke is over. The hollow part of the die has not touched the metal all the while, and we may ſay that the impreſſion was made by air. If this air eſcape by any engraving reaching through the border, they cohere inſeparably.

27 Probable cauſe why the die adheres to the coin.

We have admitted that the glaſs plates are in contact when they cohere thus firmly. But we are not certain of this: for if we take theſe cohering glaſſes, and touch them with water, it quickly inſinuates itſelf between them. Yet they ſtill cohere, but can now be pretty eaſily ſeparated.

28 Repulſion the cauſe of ſome bodies ſwimming in a fluid ſpecifically lighter than themſelves.

It is owing to this repulſion, exerted through its proper ſphere, that certain powders ſwim on the ſurface of water, and are wetted with great difficulty. Certain inſects can run about on the ſurface of water. They have bruſhy feet, which occupy a conſiderable ſurface; and if their ſteps are viewed with a magnifying glaſs, the ſurface of the water is ſeen depreſſed all around, reſembling the footſteps of a man walking on feather-beds. This is owing to a repulſion between the bruſh and the water. A common fly cannot walk in this manner on water. Its feet are wetted, becauſe they attract the water inſtead of repelling it. A ſteel needle, wiped very clean, will lie on the ſurface of water, making an impreſſion as a great bar would make on a feather bed; and its weight is leſs than that of the diſplaced water. A dew drop lies on the leaves of plants without touching them mathematically, as is plain from the extreme brilliancy of the reflection at the poſterior ſurface; nay, it may be ſometimes obſerved that the drops of rain lie on the ſurface of water, and roll about on it like balls on a table. Yet all theſe ſubſtances can be wetted; that is, water can be applied to them at ſuch diſtances that they attract it.

What we ſaid a little ago of water inſinuating itſelf between the glaſs plates without altogether deſtroying their coheſion, ſhows that this coheſion is not the ſame that obtains between the particles of one of the plates; that is, the two plates are not in the ſtate of one continued maſs. It is highly probable, therefore, that between theſe two ſtates there is an intermediate ſtate of repulſion, nay, perhaps many ſuch, alternated with attractive ſtates.

A piece of ice is elaſtic, for it rebounds and rings. Its particles, therefore, when compreſſed, reſile; and when ſtretched, contract again. The particles are therefore in the ſtate repreſented by B in figure 1. acted on by repulſive forces, if brought nearer; and by attractive forces, if drawn further aſunder. Ice expands, like all other bodies, by heat. It abſorbs a vaſt quantity of fire; which, by combining its attractions and repulſions with thoſe of the particles of ice, changes completely the law of action, without making any ſenſible change in the diſtance of the particles, and the ice becomes water. In this new ſtate the particles are again in limits between attractive and repulſive forces; for water has been ſhown, by the experiments of Canton and Zimmerman, to be elaſtic or compreſſible. It again expands by heat. It again abſorbs a prodigious quantity of heat, and becomes elaſtic vapour; its particles repelling each other at all diſtances yet obſerved. The diſtance between the particles of one plate of glaſs and thoſe of another which lies on it, and is carried by it, is a diſtance of repulſion; for the force which ſupports the upper piece is acting in oppoſition to its weight. This diſtance is leſs than that at which it would *ſuſpend* it below it with a ſilk fibre interpoſed; for no priſmatic colours appear between them when the ſilk fibre is interpoſed. But the diſtance at which glaſs attracts water is much leſs than this, for no colours appear when glaſs is wetted with water. This diſtance is leſs, and not greater, than the other; for when the glaſſes have water interpoſed between them inſtead of air, it is found, that when any particular colour appears, the thickneſs of the plate of water is to that of the plate of air which would produce the ſame colour nearly as 3 to 4. Now, if a piece of glaſs be wetted, and exhibit no colour, and another piece of glaſs be ſimply laid on it, no colour will appear; but if they are ſtrongly preſſed, the colours appear in the ſame manner as if the glaſſes had air between. Alſo, when glaſs is ſimply wetted, and the film of water is allowed to evaporate, when it is thus reduced to a proper thinneſs, the colours ſhow themſelves in great beauty.

29 Particles of matter connected by forces acting at a diſtance.

Theſe are a few of many thouſand facts, by which it is unqueſtionably proved that the particles of tangible matter are connected by forces acting at a diſtance, varying with the diſtance, and alternately attractive and repulſive. If we repreſent theſe forces as we have already done in fig. 1. by the ordinates C *c*, D *d*, E *e*, F *f*, &c. of a curve, it is evident that this curve muſt croſs the axis at all thoſe diſtances where the forces change from attractive to repulſive, and the curve muſt have branches alternately above and below the axis.

All theſe alternations of attraction and repulſion take place at ſmall and inſenſible diſtances. At all ſenſible diſtances the particles are influenced by the attraction of gravitation; and therefore this part of the curve muſt be a hyperbola whoſe equation is $y=\frac{a^3}{x^2}$. What is the form of the curve correſponding to the ſmalleſt diſtance of the particles? that is, what is the mutual action between the particles juſt before their coming into abſolute contact? Analogy ſhould lead us to ſuppoſe it to be repulſion: for ſolidity is the laſt and ſimpleſt form of bodies with which we are acquainted.—Fluids are more compounded, containing fire as an eſſential ingredient. We ſhould conclude that this ultimate repulſion is inſuperable, for the hardeſt bodies are the moſt elaſtic. We are fully entitled to ſay, that this repelling force exceeds all that we have ever yet applied to overcome it; nay, there are good reaſons for ſaying that this ultimate repulſion, by which the particles are kept from mathematical contact, is really inſuperable in its own nature, and that it is impoſſible to produce mathematical contact.

30 Mathematical contact impoſſible.

We ſhall juſt mention one of theſe, which we conſider as unanſwerable. Suppoſe two atoms, or ultimate particles of matter A and B. Let A be at reſt, and B move

move up to it with the velocity 2; and let us fuppofe that it comes into mathematical contact, and impels it (according to the common acceptation of the word). Both move with the velocity 1. This is granted by all to be the final refult of the collifion. Now the inftant of time in which this communication happens is no part either of the duration of the folitary motion of A, nor of the joint motion of A and B: It is the feparation or boundary between them. It is at once the end of the firft, and the beginning of the fecond, belonging equally to both. A was moving with the velocity 2. The diftinguifhing circumftance therefore of its mechanical ftate is, that it has a determination (however incomprehenfible) by which it would move for ever with the velocity 2, if nothing changed it. This it has during the whole of its folitary motion, and therefore in the laft inftant of this motion. In like manner, during the whole of the joint motion, and therefore in the firft inftant of this motion, the atom A has a determination by which it would move for ever with the velocity 1. In one and the fame inftant, therefore, the atom A has two incompatible determinations. Whatever notion we can form of this ftate, which we call velocity, as a diftinction of condition, the fame impoffibility of conception or the fame abfurdity occurs. Nor can it be avoided in any other way than by faying, that this change of A's motion is brought about by infenfible gradations; that is, that A and B influence each other precifely as they would do if a flender fpring were interpofed. The reader is defired to look at what we have faid in the article PHYSICS, § 82.

The two magnets there fpoken of are good reprefentatives of two atoms endowed with mutual powers of repulfion; and the communication of motion is accomplifhed in both cafes in precifely the fame manner.

If, therefore, we fhall ever be fo fortunate as to difcover the law of variation of that force which connects one ATOM of matter with another atom, and which is therefore characteriftic of matter, and the ultimate fource of all its fenfible qualities, the curve whofe ordinates reprefent the kind and the intenfity of this atomical force

Fig. 2. will be fomething like that fketched in fig. 2. The firft branch $a\,n$ B will have AK (perpendicular to the axis AH) for its affymptote, and the laft branch $l\,m\,o$ will be to all fenfe a hyperbola, having AO for its affymptote; and the ordinates l L, m M, &c. will be proportional to $\frac{1}{\mathrm{AL}^2}$, $\frac{1}{\mathrm{AM}^2}$, &c. expreffing the univerfal gravitation of matter. It will have many branches B b C, D d E, F f G, &c. expreffing attractions, and alternate repulfive branches C c D, E e F, G g H, &c. All thefe will be contained within a diftance AH, which does not exceed a very minute fraction of an inch.

31
The fimpleft extended particle confifts of four atoms.

The fimpleft particle which can be a conftituent of a body having length, breadth, and thicknefs, muft confift of four fuch atoms, all of which combine their influence on each atom of another fuch particle. It is evident that the curve which expreffes the forces that connect two fuch particles muft be totally different from this original curve, this hylarchic principle. Suppofing the laft known, our mathematical knowledge is quite able to difcover the firft: but when we proceed to compofe a body of particles, each of which confifts of four fuch particles, we may venture to fay, that the compound force which connects them is almoft beyond our fearch, and that the difcovery of the primary force from an *accurate* knowledge of the corpufcular forces of *this* particular matter is abfolutely out of our power.

All that we can learn is, the poffibility, nay the certainty, of an innumerable variety of external fenfible forms and qualities, by which different kinds of matter will be diftinguifhed, arifing from the number, the order of compofition, and the arrangement of the fubordinate particles of which a particle of this or that kind of matter is compofed. All thefe varieties will take place at thofe fmall and infenfible diftances which are between A and H, and may produce all that variety which we obferve in the tangible or mechanical forms of bodies, fuch as elafticity, ductility, hardnefs, foftnefs, fluidity, vapour, and all thofe unfeen motions or actions which we obferve in fufion and congelation, evaporation and condenfation, folution and precipitation, cryftallization, vegetable and animal affimilation and fecretion, &c. &c. &c. while all bodies muft be, in a certain degree, elaftic, all muft gravitate, and all muft be incompenetrable.

This general and fatisfactory refemblance between the appearance of tangible matter and the legitimate confequence of this general hypothetical property of an atom of matter, affords a confiderable probability that fuch is the origin of all the phenomena. We earneftly recommend to our readers a *careful* perufal of Bofcovich's celebrated treatife. A careful perufal is neceffary for feeing its value; and nothing will be got by a hafty look at it. The reader will be particularly pleafed with the facility and evidence with which the ingenious author has deduced all the ordinary principles of mechanics, and with the explanation which he has given of fluidity, and his deduction from thence of the laws of hydroftatics. No part of the treatife is more valuable than the doctrine of the propagation of preffure through folid bodies. This, however, is but juft touched on in the courfe of the inveftigation of the principles of mechanics. We fhall borrow as much as will fuffice for our prefent inquiry into the ftrength of materials; and we truft that our readers are not difpleafed with this general fketch of the doctrine (if it may be fo called) of the cohefion of bodies. It is curious and important in itfelf, and is the foundation of all the knowledge we can acquire of the prefent article. We are forry to fay that it is as yet a new fubject of ftudy; but it is a very promifing one, and we by no means defpair of feeing the whole of chemiftry brought by its means within the pale of mechanical fcience. The great and diftinguifhing agent in chemiftry is heat, or fire the caufe of heat; and one of its moft fingular effects is the converfion of bodies into elaftic vapour. We have the cleareft evidence that this is brought about by mechanical forces: for it can be oppofed or prevented by external preffure, a very familiar mechanical force. We may perhaps find another mechanical force which will prevent fufion.

32
The doctrine of cohefion yet a new fubject.

HAVING now made our readers familiar with the mode of action in which cohefion operates in giving ftrength to folid bodies, we proceed to confider the ftrains to which this ftrength is oppofed.

33
Strains to which ftrength is oppofed.

A piece of folid matter is expofed to four kinds of ftrains, pretty different in the manner of their operation.

1. It may be torn afunder, as in the cafe of ropes, ftretchers, king-pofts, tye-beams, &c.

2.

2. It may be cruſhed, as in the caſe of pillars, poſts, and truſs beams.

3. It may be broken acroſs, as happens to a joiſt or lever of any kind.

4. It may be wrenched or twiſted, as in the caſe of the axle of a wheel, the nail of a preſs, &c.

I. It may be pulled asunder.

34 Matter may be pulled aſunder.

This is the ſimpleſt of all ſtrains, and the others are indeed modifications of it. To this the force of coheſion is *directly* oppoſed, with very little modification of its action by any particular circumſtances.

When a long cylindrical or priſmatic body, ſuch as a rod of wood or metal, or a rope, is drawn by one end, it muſt be reſiſted at the other, in order to bring its coheſion into action. When it is faſtened at one end, we cannot conceive it any other way than as equally ſtretched in all its parts; for all our obſervations and experiments on natural bodies concur in ſhowing us that the forces which connect their particles, in any way whatever, are equal and oppoſite. This is called the *third law of motion*; and we admit its univerſality, while we affirm that it is purely experimental (ſee Physics). Yet we have met with diſſertations by perſons of eminent knowledge, where propoſitions are maintained inconſiſtent with this. During the diſpute about the communication of motion, ſome of the ableſt writers have ſaid, that a ſpring compreſſed or ſtretched at the two ends was gradually leſs and leſs compreſſed or ſtretched from the extremities towards the middle: but the ſame writers acknowledged the univerſal equality of action and reaction, which is quite incompatible with this ſtate of the ſpring. No ſuch inequality of compreſſion or dilatation has ever been obſerved; and a little reflection will ſhow it to be impoſſible, in conſiſtency with the equality of action and reaction.

Since all parts are thus equally ſtretched, it follows, that the ſtrain in any tranſverſe ſection is the ſame, as alſo in every point of that ſection. If therefore the body be ſuppoſed of a homogeneous texture, the coheſion of the parts is equable; and ſince every part is equally ſtretched, the particles are drawn to equal diſtances from their quieſcent poſitions, and the forces which are thus excited and now exerted in oppoſition to the ſtraining force, are equal. This external force may be increaſed by degrees, which will gradually ſeparate the parts of the body more and more from each other, and the connecting forces increaſe with this increaſe of diſtance, till at laſt the coheſion of ſome particles is overcome. This muſt be immediately followed by a rupture, becauſe the remaining forces are now weaker than before.

It is the united force of coheſion, immediately before the diſunion of the firſt particles, that we call the strength of the ſection. It may alſo be properly called its absolute strength, being exerted in the ſimpleſt form, and not modified by any relation to other circumſtances.

35 A circumſtance to be attended to in every conſtruction requiring ſtrength.

If the external force has not produced any permanent change on the body, and it therefore recovers its former dimenſions when the force is withdrawn, it is plain that this ſtrain may be repeated as often as we pleaſe, and the body which withſtands it once will always withſtand it. It is evident that this ſhould be attended to in all conſtructions, and that in all our inveſtigations on this ſubject this ſhould be kept ſtrictly in view. When we treat a piece of ſoft clay in this manner, and with this precaution, the force employed muſt be very ſmall. If we exceed this, we produce a permanent change. The rod of clay is not indeed torn aſunder; but it has become ſomewhat more ſlender: the number of particles in a croſs ſection is now ſmaller; and therefore, although it will again, in this new form, ſuffer, or allow an endleſs repetition of a *certain* ſtrain without any farther permanent change, this ſtrain is ſmaller than the former.

Something of the ſame kind happens in all bodies which receive a sett by the ſtrain to which they are expoſed. All ductile bodies are of this kind. But there are many bodies which are not ductile. Such bodies break completely whenever they are ſtretched beyond the limit of their perfect elaſticity. Bodies of a fibrous ſtructure exhibit very great varieties in their coheſion. 36

36 Great varieties in coheſion, but

In ſome the fibres have no lateral coheſion, as in the caſe of a rope. The only way in which all the fibres can be made to unite their ſtrength is, to twiſt them together. This cauſes them to bind each other ſo faſt, that any one of them will break before it can be drawn out of the bundle. In other fibrous bodies, ſuch as timber, the fibres are held together by ſome cement or gluten. This is ſeldom as ſtrong as the fibre. Accordingly timber is much eaſier pulled aſunder in a direction tranſverſe to the fibres. There is, however, every poſſible variety in this particular.

In ſtretching and breaking fibrous bodies, the viſible extenſion is frequently very conſiderable. This is not ſolely the increaſing of the diſtance of the particles of the cohering fibre: the greateſt part chiefly ariſes from drawing the crooked fibre ſtraight. In this, too, there is great diverſity; and it is accompanied with important differences in their power of withſtanding a ſtrain. In ſome woods, ſuch as fir, the fibres on which the ſtrength moſt depends are very ſtraight. Such woods are commonly very elaſtic, do not take a ſett, and break abruptly when overſtrained: others, ſuch as oak and birch, have their reſiſting fibres very undulating and crooked, and ſtretch very ſenſibly by a ſtrain. They are very liable to take a ſet, and they do not break ſo ſuddenly, but give warning by *complaining*, as the carpenters call it; that is, by giving viſible ſigns of a derangement of texture. Hard bodies of an uniform glaſſy ſtructure, or granulated like ſtones, are elaſtic through the whole extent of their coheſion, and take no ſett, but break at once when overloaded.

Notwithſtanding the immenſe variety which nature exhibits in the ſtructure and coheſion of bodies, there are certain general facts of which we may now avail ourſelves with advantage. In particular, 37

37 The abſolute coheſion or ſtrength proportional to the area of the ſection perpendicular to the extending force.

The abſolute coheſion is proportional to the area of the ſection. This muſt be the caſe where the texture is perfectly uniform, as we have reaſon to think it is in glaſs and the ductile metals. The coheſion of each particle being alike, the whole coheſion muſt be proportional to their number, that is, to the area of the ſection. The ſame muſt be admitted with reſpect to bodies of a granulated texture, where the granulation is regular and uniform. The ſame muſt be admitted of fibrous bodies, if we ſuppoſe their fibres equally ſtrong, equally denſe, denfe, and fimilarly difpofed through the whole fection; and this we muft either fuppofe, or muft ftate the diverfity, and meafure the cohefion accordingly.

We may therefore affert, as a general propofition on this fubject, that the abfolute ftrength in any part of a body by which it refifts being pulled afunder, or the force which muft be employed to tear it afunder *in that part*, is proportional to the area of the fection perpendicular to the extending force.

Therefore all cylindrical or prifmatical rods are equally ftrong in every part, and will break alike in any part; and bodies which have unequal fections will always break in the flendereft part. The length of the cylinder or prifm has no effect on the ftrength; and the vulgar notion, that it is eafier to break a very long rope than a fhort one, is a very great miftake. Alfo the abfolute ftrengths of bodies which have fimilar fections are proportional to the fquares of their diameters or homologous fides of the fection.

The weight of the body itfelf may be employed to ftrain it and to break it. It is evident, that a rope may be fo long as to break by its own weight. When the rope is hanging perpendicularly, although it is equally ftrong in every part, it will break towards the upper

38 Relative ftrength.

end, becaufe the ftrain on any part is the weight of all that is below it. Its RELATIVE STRENGTH in any part, or power of withftanding the ftrain which is actually laid on it, is inverfely as the quantity below that part.

When the rope is ftretched horizontally, as in towing a fhip, the ftrain arifing from its weight often bears a very fenfible proportion to its whole ftrength.

Fig. 3. Let AEB (fig. 3.) be any portion of fuch a rope, and AC, BC be tangents to the curve into which its gravity bends it. Complete the parallelogram ACBD. It is well known that the curve is a catenaria, and that DC is perpendicular to the horizon; and that DC is to AC as the weight of the rope AEB to the ftrain at A.

In order that a fufpended heavy body may be equally able in every part to carry its own weight, the fection in that part muft be proportional to the folid contents of all that is below it. Suppofe it a conoidal fpindle, formed by the revolution of the curve A a e

Fig. 4. (fig. 4.) round the axis CE. We muft have $AC^2 : ac^2 = AEB$ fol. : a E b fol. This condition requires the logarithmic curve for A a c, of which C c is the axis.

Thefe are the chief general rules which can be fafely deduced from our cleareft notions of the cohefion of bodies. In order to make any practical ufe of them, it is proper to have fome meafures of the cohefion of fuch bodies as are commonly employed in our mechanics, and other ftructures where they are expofed to this kind of

39 The cohefion of metals depends on various circumftances

ftrain. Thefe muft be deduced folely from experiment. Therefore they muft be confidered as no more than general values, or as the averages of many particular trials. The irregularities are very great, becaufe none of the fubftances are conftant in their texture and firmnefs. Metals differ by a thoufand circumftances unknown to us, according to their purity, to the heat with which they were melted, to the moulds in which they were caft, and the treatment they have afterwards received, by forging, wire-drawing, tempering, &c.

It is a very curious and inexplicable fact, that by forging a metal, or by frequently drawing it through a fmooth hole in a fteel plate, its cohefion is greatly increafed. This operation undoubtedly deranges the natural fituation of the particles. They are fqueezed clofer together in one direction; but it is not in the direction in which they refift the fracture. In this direction they are rather feparated to a greater diftance. The general denfity, however, is augmented in all of them except lead, which grows rather rarer by wire-drawing; but its cohefion may be more than tripled by this operation. Gold, filver, and brafs, have their cohefion nearly tripled; copper and iron have it more than doubled. In this operation they alfo grow much harder. It is proper to heat them to rednefs after drawing a little. This is called *nealing* or *annealing*. It foftens the metal again, and renders it fufceptible of another drawing without the rifk of cracking in the operation.

We do not pretend to give any explanation of this remarkable and very important fact, which has fomething refembling it in woods and other fibrous bodies, as will be mentioned afterwards.

The varieties in the cohefion of ftones and other minerals, and of vegetable and animal fubftances, are hardly fufceptible of any defcription or claffification.

40 Cohefion and ftrength of different metals.

We fhall take for the meafure of cohefion the number of pounds avoirdupois which are juft fufficient to tear afunder a rod or bundle of one inch fquare. From this it will be eafy to compute the ftrength correfponding to any other dimenfion.

(A) This was an experiment by Mufchenbroek, to examine the vulgar notion that iron forged from old horfe nails was ftronger than all others, and fhows its falfity.

41 Tenacity of metals increaſed by mixtures.

It is very remarkable that almoſt all the mixtures of metals are more tenacious than the metals themſelves. The change of tenacity depends much on the proportion of the ingredients, and the proportion which produces the moſt tenacious mixture is different in the different metals. We have ſelected the following from the experiments of Muſchenbroek. The proportion of ingredients here ſelected is that which produces the greateſt ſtrength.

Two parts of gold with one of ſilver -	28,000
Five parts of gold with one of copper -	50,000
Five parts of ſilver with one of copper -	48,500
Four parts of ſilver with one of tin -	41,000
Six parts of copper with one of tin -	41,000
Five parts of Japan copper with one of Banca tin - - - - . - -	57,000
Six parts of Chili copper with one of Malacca tin - - - -	60,000
Six parts of Swediſh copper with one of Malacca tin - - -	64,000
Braſs conſiſts of copper and zinc in an unknown proportion; its ſtrength is	51,000
Three parts of block tin with one part of lead - - - -	10,200
Eight parts of block tin with one part of zinc - - - -	10,000
Four parts of Malacca tin with one part of regulus of antimony . -	12,000
Eight parts of lead with one of zinc -	4,500
Four parts of tin with one of lead and one of zinc - - -	13,000

Theſe numbers are of conſiderable uſe in the arts. The mixtures of copper and tin are particularly intereſting in the fabric of great guns. We ſee that, by mixing copper whoſe greateſt ſtrength does not exceed 37,000, with tin which does not exceed 6000, we produce a metal whoſe tenacity is almoſt double, at the ſame time that it is harder and more eaſily wrought. It is, however, more fuſible, which is a great inconvenience. We alſo ſee that a very ſmall addition of zinc almoſt doubles the tenacity of tin, and increaſes the tenacity of lead five times; and a ſmall addition of lead doubles the tenacity of tin. Theſe are economical mixtures. This is a very valuable information to the plumbers for augmenting the ſtrength of water-pipes.

By having recourſe to theſe tables, the engineer can proportion the thickneſs of his pipes (of whatever metal) to the preſſures to which they are expoſed.

2d, Woods.

We may premiſe to this part of the table the following general obſervations.

42 Tenacity or ſtrength of wood.

1. The wood immediately ſurrounding the pith or heart of the tree is the weakeſt, and its inferiority is ſo much more remarkable as the tree is older. In this aſſertion, however, we ſpeak with ſome heſitation. Muſchenbroek's *detail* of experiments is decidedly in the affirmative. M Buffon, on the other hand, ſays, that his experience has taught him that the heart of a ſound tree is the ſtrongeſt; but he gives no inſtances. We are certain, from many obſervations of our own, on very *large* oaks and firs, that the heart is much weaker than the exterior parts.

2. The wood next the bark, commonly called the *white* or *blea*, is alſo weaker than the reſt; and the wood gradually increaſes in ſtrength as we recede from the centre to the blea.

3. The wood is ſtronger in the middle of the trunk than at the ſpringing of the branches or at the root; and the wood of the branches is weaker than that of the trunk.

4. The wood of the north ſide of all trees which grow in our European climates is the weakeſt, and that of the ſouth-eaſt ſide is the ſtrongeſt; and the difference is moſt remarkable in hedge-row trees, and ſuch as grow ſingly. The heart of a tree is never in its centre, but always nearer to the north ſide, and the annual coats of wood are thinner on that ſide. In conformity with this, it is a general opinion of carpenters that timber is ſtronger whoſe annual plates are thicker. The trachea or air-veſſels are weaker than the ſimple ligneous fibres. Theſe air-veſſels are the ſame in diameter and number of rows in trees of the ſame ſpecies, and they make the viſible ſeparation between the annual plates. Therefore when theſe are thicker, they contain a greater proportion of the ſimple ligneous fibres.

5. All woods are more tenacious while green, and loſe very conſiderably by drying after the trees are felled.

The only author who has put it in our power to judge of the propriety of his experiments is Muſchenbroek. He has deſcribed his method of trial minutely; and it ſeems unexceptionable. The woods were all formed into ſlips fit for his apparatus, and part of the ſlip was cut away to a parallelopiped of $\frac{1}{5}$th of an inch ſquare, and therefore $\frac{1}{25}$th of a ſquare inch in ſection. The abſolute ſtrengths of a ſquare inch were as follow:

43 Abſolute ſtrength of different kinds of wood.

	lib.		lib.
Locuſt tree	20,100	Pomegranate	9,750
Jujeb -	18,500	Lemon	9,250
Beech, oak	17,300	Tamarind	8,750
Orange -	15,500	Fir -	8,330
Alder -	13,900	Walnut -	8,130
Elm -	13,200	Pitch pine	7,650
Mulberry -	12,500	Quince -	6,750
Willow -	12,500	Cypreſs -	6,000
Aſh -	12,000	Poplar -	5,500
Plum -	11,800	Cedar -	4,880
Elder -	10,000		

Mr Muſchenbroek has given a very minute detail of the experiments on the aſh and the walnut, ſtating the weights which were required to tear aſunder ſlips taken from the four ſides of the tree, and on each ſide, in a regular progreſſion from the centre to the circumference. The numbers of this table correſponding to theſe two timbers may therefore be conſidered as the average of more than 50 trials made of each; and he ſays that all the others were made with the ſame care. We cannot therefore ſee any reaſon for not confiding in the reſults; yet they are conſiderably higher than thoſe given by ſome other writers. Mr Pitot ſays, on the authority of his own experiments, and of theſe of Mr Parent, that 60 pounds will juſt tear aſunder a ſquare line of ſound oak, and that it will bear 50 with ſafety. This gives 8640 for the utmoſt ſtrength of a ſquare inch, which is much inferior to Muſchenbroek's valuation.

We may add to theſe,

Ivory

Strength of Materials.

44
and of other substances.

Ivory	16,270
Bone	5,250
Horn	8,750
Whalebone	7,500
Tooth of sea-calf	4,075

45
No substance to be strained in architecture above one half its strength.

The reader will surely observe, that these numbers express something more than the utmost cohesion; for the weights are such as will very quickly, that is, in a minute or two, tear the rods asunder. It may be said in general, that two thirds of these weights will sensibly impair the strength after a considerable while, and that one-half is the utmost that can remain suspended at them without risk for ever; and it is this last allotment that the engineer should reckon upon in his constructions. There is, however, considerable difference in this respect. Woods of a very straight fibre, such as fir, will be less impaired by any load which is not sufficient to break them immediately.

According to Mr Emerson, the load which may be safely suspended to an inch square is as follows:

Iron	76,400
Brass	35,600
Hempen rope	19,600
Ivory	15,700
Oak, box, yew, plum-tree	7,850
Elm, ash, beech	6,070
Walnut, plum	5,360
Red fir, holly, elder, plane, crab	5,000
Cherry, hazel	4,760
Alder, asp, birch, willow	4,290
Lead	430
Freestone	914

He gives us a practical rule, that a cylinder whose diameter is d inches, loaded to one-fourth of its absolute strength, will carry as follows:

Iron	135	Cwt.
Good rope	22	
Oak	14	
Fir	9	

The rank which the different woods hold in this list of Mr Emerson's is very different from what we find in Muschenbroek's. But precise measures must not be expected in this matter. It is wonderful that in a matter of such unquestionable importance the public has not enabled some persons of judgement to make proper trials. They are beyond the abilities of private persons.

II. Bodies may be crushed.

46
It is of importance to know what will crush bodies.

It is of equal, perhaps greater, importance to know the strain which may be laid on solid bodies without danger of crushing them. Pillars and posts of all kinds are exposed to this strain in its simplest form; and there are cases where the strain is enormous, viz. where it arises from the oblique position of the parts; as in the struts, braces, and trusses, which occur very frequently in our great works.

It is therefore most desirable to have some general knowledge of the principle which determines the strength of bodies in opposition to this kind of strain. But unfortunately we are much more at a loss in this than in the last case. The mechanism of nature is much more complicated in the present case. It must be in some circuitous way that compression can have any tendency to tear asunder the parts of a solid body, and it is very difficult to trace the steps.

If we suppose the particles insuperably hard and in contact, and disposed in lines which are in the direction of the external pressures, it does not appear how any pressure can disunite the particles; but this is a gratuitous supposition. There are infinite odds against this precise arrangement of the lines of particles; and the compressibility of all kinds of matter in some degree shows that the particles are in a situation equivalent to distance. This being the case, and the particles, with their intervals, or what is equivalent to intervals, being in situations that are oblique with respect to the pressures, it must follow, that by squeezing them together in one direction, they are made to bulge out or separate in other directions. This may proceed so far that some may be thus pushed laterally beyond their limits of cohesion. The moment that this happens the resistance to compression is diminished, and the body will now be crushed together. We may form some notion of this by supposing a number of spherules, like small shot, sticking together by means of a cement. Compressing this in some particular direction causes the spherules to act among each other like so many wedges, each tending to penetrate through between the three which lie below it: and this is the simplest, and perhaps the only distinct, notion we can have of the matter. We have reason to think that the constitution of very homogeneous bodies, such as glass, is not very different from this. The particles are certainly arranged symmetrically in the angles of some regular solids. It is only such an arrangement that is consistent with transparency, and with the free passage of light in *every* direction.

47
Their strength or power of resistance to such a force

If this be the constitution of bodies, it appears probable that the strength, or the resistance which they are capable of making to an attempt to crush them to pieces, is proportional to the area of the section whose plane is perpendicular to the external force; for each particle being similarly and equally acted on and resisted, the whole resistance must be as their number; that is, as the extent of the section.

Accordingly this principle is assumed by the few writers who have considered this subject; but we confess that it appears to us very doubtful. Suppose a number of brittle or friable balls lying on a table uniformly arranged, but not cohering nor in contact, and that a board is laid over them and loaded with a weight; we have no hesitation in saying, that the weight necessary to crush the whole collection is proportional to their number or to the area of the section. But when they are in contact (and still more if they cohere), we imagine that the case is materially altered. Any individual ball is crushed only in consequence of its being bulged outwards in the direction perpendicular to the pressure employed. If this could be prevented by a hoop put round the ball like an equator, we cannot see how any force can crush it. Any thing therefore which makes this bulging outwards more difficult, makes a greater force necessary. Now this effect will be produced by the mere contact of the balls before the pressure is applied; for the central ball cannot swell outward laterally without pushing away the balls on all sides of it. This is prevented by the friction on the table and upper board

Strength of Materials.

of board, which is at leaſt equal to one third of the preſſure. Thus any interior ball becomes ſtronger by the mere vicinity of the others; and if we farther ſuppoſe them to cohere laterally, we think that its ſtrength will be ſtill more increaſed.

The analogy between theſe balls and the cohering particles of a friable body is very perfect. We ſhould therefore expect that the ſtrength by which it reſiſts being cruſhed will increaſe in a greater ratio than that of the ſection, or the ſquare of the diameter of ſimilar ſections; and that a ſquare inch of any matter will bear a greater weight in proportion as it makes a part of a greater ſection. Accordingly this appears in many experiments, as will be noticed afterwards. Muſchenbroek, Euler, and ſome others, have ſuppoſed the ſtrength of columns to be as the biquadrates of their diameters. But Euler deduced this from formulæ which occurred to him in the courſe of his algebraic analyſis; and he boldly adopts it as a principle, without looking for its foundation in the phyſical aſſumptions which he had made in the beginning of his inveſtigation. But ſome of his original aſſumptions were as paradoxical, or at leaſt as gratuitous, as theſe reſults: and thoſe, in particular, from which this proportion of the ſtrength of columns was deduced, were almoſt foreign to the caſe; and therefore the inference was of no value. Yet it was received as a principle by Muſchenbroek and by the academicians of St Peterſburgh. We make theſe very few obſervations, becauſe the ſubject is of great practical importance; and it is a great obſtacle to improvements when deference to a great name, joined to incapacity or indolence, cauſes authors to adopt his careleſs reveries as principles from which they are afterwards to draw important conſequences. It muſt be acknowledged that we have not as yet eſtabliſhed the relation between the dimenſions and the ſtrength of a pillar on ſolid mechanical principles. Experience plainly contradicts the general opinion, that the ſtrength is proportional to the area of the ſection; but it is ſtill more inconſiſtent with the opinion, that it is in the quadruplicate ratio of the diameters of ſimilar ſections. It would ſeem that the ratio depends much on the internal ſtructure of the body; and experiment ſeems the only method for aſcertaining its general laws.

48 to be aſcertained only by experiment.

If we ſuppoſe the body to be of a fibrous texture, having the fibres ſituated in the direction of the preſſure, and ſlightly adhering to each other by ſome kind of cement, ſuch a body will fail only by the bending of the fibres, by which they will break the cement and be detached from each other. Something like this may be ſuppoſed in wooden pillars. In ſuch caſes, too it would appear that the reſiſtance muſt be as the number of equally reſiſting fibres, and as their mutual ſupport, jointly; and, therefore, as ſome function of the area of the ſection. The ſame thing muſt happen if the fibres are naturally crooked or undulated, as is obſerved in many woods, &c. provided we ſuppoſe ſome ſimilarity in their form. Similarity of ſome kind muſt always be ſuppoſed, otherwiſe we need never aim at any general inferences.

In all caſes therefore we can hardly refuſe admitting that the ſtrength in oppoſition to compreſſion is proportional to a function of the area of the ſection.

As the whole length of a cylinder or priſm is equally preſſed, it does not appear that the ſtrength of a pillar is at all affected by its length. If indeed it be ſuppoſed to bend under the preſſure, the caſe is greatly changed, becauſe it is then expoſed to a tranſverſe ſtrain; and this increaſes with the length of the pillar. But this will be conſidered with due attention under the next claſs of ſtrains.

Few experiments have been made on this ſpecies of ſtrength and ſtrain. Mr Petit ſays, that his experiments and thoſe of Mr Parent, ſhow that the force neceſſary for cruſhing a body is nearly equal to that which will tear it aſunder. He ſays that it requires ſomething more than 60 pounds on every ſquare line to cruſh a piece of ſound oak. But the rule is by no means general: Glaſs, for inſtance, will carry a hundred times as much as oak in this way, that is, reſting on it; but will not *ſuſpend* above four or five times as much. Oak will ſuſpend a great deal more than fir; but fir will carry twice as much as a pillar. Woods of a ſoft texture, although conſiſting of very tenacious fibres, are more eaſily cruſhed by their load. This ſoftneſs of texture is chiefly owing to their fibres not being ſtraight but undulated, and there being conſiderable vacuities between them, ſo that they are eaſily bent laterally and cruſhed. When a poſt is overſtrained by its load, it is obſerved to ſwell ſenſibly in diameter. Increaſing the load cauſes longitudinal cracks or ſhivers to appear, and it preſently after gives way. This is called *crippling*.

In all caſes where the fibres lie oblique to the ſtrain the ſtrength is greatly diminiſhed, becauſe the parts can then be made to ſlide on each other, when the coheſion of the cementing matter is overcome.

Moſchenbroek has given ſome experiments on this ſubject; but they are caſes of long pillars, and therefore do not belong to this place. They will be conſidered afterwards.

The only experiments of which we have ſeen any detail (and it is uſeleſs to inſert mere aſſertions) are thoſe of Mr Gauthey, in the 4th volume of Rozier's *Journal de Phyſique*. This engineer expoſed to great preſſures ſmall rectangular parallelopipeds, cut from a great variety of ſtones, and noted the weights which cruſhed them. The following table exhibits the medium reſults of many trials on two very uniform kinds of freeſtone, one of them among the hardeſt and the other among the ſofteſt uſed in building.

Column 1ſt expreſſes the length AB of the ſection in French lines or 12ths of an inch; column 2d expreſſes the breadth BC; column 3d is the area of the ſection in ſquare lines; column 4th is the number of ounces required to cruſh the piece; column 5th is the weight which was then borne by each ſquare line of the ſection; and column 6th is the round numbers to which Mr Gauthey imagines that thoſe in column 5th approximate.

49 Experiments for this purpoſe made on freeſtone

Little

Strength of Materials.

Little can be deduced from theſe experiments: The 1ſt and 3d, compared with the 5th and 6th, ſhould furniſh ſimilar reſults; for the 1ſt and 5th are reſpectively half of the 3d and 6th: but the 3d is three times ſtronger (that is, a line of the 3d) than the firſt, whereas the 6th is only twice as ſtrong as the 5th.

It is evident, however, that the ſtrength increaſes much faſter than the area of the ſection, and that a ſquare line can carry more and more weight, according as it makes a part of a larger and larger ſection. In the ſeries of experiments on the ſoft ſtone, the individual ſtrength of a ſquare line ſeems to increaſe nearly in the proportion of the ſection of which it makes a part.

Mr Gauthey deduces, from the whole of his numerous experiments, that a pillar of hard ſtone of Givry, whoſe ſection is a ſquare foot, will bear with perfect ſafety 664,000 pounds, and that its extreme ſtrength is 871,000, and the ſmalleſt ſtrength obſerved in any of his experiments was 460,000. The ſoft bed of Givry ſtone had for its ſmalleſt ſtrength 187,000, for its greateſt 311,000, and for its ſafe load 249,000. Good brick will carry with ſafety 320,000; chalk will carry only 9000. The boldeſt piece of architecture in this reſpect which he has ſeen is a pillar in the church of All-Saints at Angers. It is 24 feet long and 11 inches ſquare, and is loaded with 60,000, which is not one-ſeventh of what is neceſſary for cruſhing it.

We may obſerve here by the way, that Mr Gauthey's meaſure of the ſuſpending ſtrength of ſtone is vaſtly ſmall in proportion to its power of ſupporting a load laid above it. He finds that a priſm of the hard bed of Givry, of a foot ſection, is torn aſunder by 4600 pounds; and if
50 it be firmly fixed horizontally in a wall, it will be broken
not ſatisfactory. by a weight of 56,000 ſuſpended a foot from the wall. If it reſt on two props at a foot diſtance, it will be broken by 206,000 laid on its middle. Theſe experiments agree ſo ill with each other, that little uſe can be made of them. The ſubject is of great importance, and well
51 deſerves the attention of the patriotic philoſopher.

Good experiments much wanted. A ſet of good experiments would be very valuable, becauſe it is againſt this kind of ſtrain that we muſt guard by judicious conſtruction in the moſt delicate and difficult problems which come through the hands of the civil and military engineer. The conſtruction of ſtone arches, and the conſtruction of great wooden bridges, and particularly the conſtruction of the frames of carpentry called *centres* in the erection of ſtone bridges, are the moſt difficult jobs that occur. In the centres on which the arches of the bridge of Orleans were built ſome of the pieces of oak were carrying upwards of two tons on every ſquare inch of their ſcantling. All who ſaw it ſaid that it was not able to carry the fourth part of the intended load. But the engineer underſtood the principles of his art, and ran the riſk: and the reſult completely juſtified his confidence; for the centre did not complain in any part, only it was found too ſupple; ſo that it went out of ſhape while the haunches only of the arch were laid on it. The engineer corrected this by loading it at the crown, and thus kept it completely in ſhape during the progreſs of the work.

In the Memoirs (old) of the Academy of Peterſburgh for 1778, there is a diſſertation by Euler on this ſubject, but particularly limited to the ſtrain on columns, in which the bending is taken into the account. Mr Fuſs has treated the ſame ſubject with relation to carpentry in a ſubſequent volume. But there is little in theſe papers beſides a dry mathematical diſquiſition, proceeding on aſſumptions which (to ſpeak favourably) are extremely gratuitous. The moſt important conſequence of the compreſſion is wholly overlooked, as we ſhall preſently ſee. Our knowledge of the mechaniſm of coheſion is as yet far too imperfect to entitle us to a confident application of mathematics. Experiments ſhould be multiplied.

52 How they are to be made uſeful.

The only way we can hope to make theſe experiments uſeful is to pay a careful attention to the *manner* in which the fracture is produced. By diſcovering the general reſemblances in this particular, we advance a ſtep in our power of introducing mathematical meaſurement. Thus, when a cubical piece of chalk is ſlowly cruſhed between the chaps of a vice, we ſee it uniformly ſplit in a ſurface oblique to the preſſure, and the two parts then ſlide along the ſurface of fracture. This ſhould lead us to examine mathematically what relation there is between this ſurface of fracture and the neceſſary force; then we ſhould endeavour to determine experimentally the poſition of this ſurface. Having diſcovered ſome general law or reſemblance in this circumſtance, we ſhould try what mathematical hypotheſis will agree with this. Having found one, we may then apply our ſimpleſt notions of coheſion, and compare the reſult of our computations with experiment. We are authoriſed to ſay, that a ſeries of experiments have been made in this way, and that their reſults have been very uniform, and therefore ſatisfactory, and that they will ſoon be laid before the public as the foundations of ſucceſsful practice in the conſtruction of arches.

III. A Body may be broken across.

53 It is of importance to know what ſtrain will break a body tranſverſely.

The moſt uſual, and the greateſt ſtrain, to which materials are expoſed, is that which tends to break them tranſverſely. It is ſeldom, however, that this is done in a manner perfectly ſimple; for when a beam projects horizontally from a wall, and a weight is ſuſpended from its extremity, the beam is commonly broken near the wall, and the intermediate part has performed the functions of a lever. It ſometimes, though rarely, happens that the pin in the joint of a pair of pincers or ſciſſars is cut through by the ſtrain; and this is almoſt the only caſe of a ſimple tranſverſe fracture. Being ſo rare, we may content ourſelves with ſaying, that in this caſe the ſtrength of the piece is proportional to the area of the ſection.

54 Experiments made to aſcertain it.

Experiments were made for diſcovering the reſiſtances made by bodies to this kind of ſtrain in the following manner: Two iron bars were diſpoſed horizontally at an inch diſtance; a third hung perpendicularly between them, being ſupported by a pin made of the ſubſtance to be examined. This pin was made of a priſmatic form, ſo as to fit exactly the holes in the three bars, which were made very exact, and of the ſame ſize and ſhape. A ſcale was ſuſpended at the lower end of the perpendicular bar, and loaded till it tore out that part of the pin which filled the middle hole. This weight was evidently the meaſure of the lateral coheſion of two ſections. The ſide-bars were made to graſp the middle bar pretty ſtrongly between them, that there might be no diſtance impoſed between the oppoſite preſſures. This would have combined the energy of a lever with the purely tranſverſe preſſure. For the ſame reaſon it was neceſ-

ſary

Strength of Materials. sary that the internal parts of the holes should be no smaller than the edges. Great irregularities occurred in our first experiments from this cause, because the pins were somewhat tighter within than at the edges; but when this was corrected they were extremely regular. We employed three sets of holes, viz. a circle, a square (which was occasionally made a rectangle whose length was twice its breadth), and an equilateral triangle. We found in all our experiments the strength exactly proportional to the area of the section, and quite independent of its figure or position, and we found it considerably above the direct cohesion; that is, it took considerably more than twice the force to tear out this middle piece than to tear the pin asunder by a direct pull. A piece of fine freestone required 205 pounds to pull it directly asunder, and 575 to break it in this way. The difference was very constant in any one substance, but varied from four-thirds to six-thirds in different kinds of matter, being smallest in bodies of a fibrous texture. But indeed we could not make the trial on any bodies of considerable cohesion, because they required such forces as our apparatus could not support. Chalk, clay baked in the sun, baked sugar, brick, and freestone, were the strongest that we could examine.

55 Their result.

But the more common case, where the energy of a lever intervenes, demands a minute examination.

56 The strength of a lever. Fig. 5.

Let DABC (fig. 5.) be a vertical section of a prismatic solid (that is, of equal size throughout), projecting horizontally from a wall in which it is firmly fixed; and let a weight P be hung on it at B, or let any power P act at B in a direction perpendicular to AB. Suppose the body of insuperable strength in every part except in the vertical section DA, perpendicular to its length. It must break in this section only. Let the cohesion be uniform over the whole of this section; that is, let each of the adjoining particles of the two parts cohere with an equal force f.

There are two ways in which it may break. The part ABCD may simply slide down along the surface of fracture, provided that the power acting at B is equal to the accumulated force which is exerted by every particle of the section in the direction AD.

But suppose this effectually prevented by something that supports the point A. The action at P tends to make the body turn round A (or round a horizontal line passing through A at right angles to AB) as round a joint. This it cannot do without separating at the line DA. In this case the adjoining particles at D or at E will be separated horizontally. But their cohesion resists this separation. In order, therefore, that the fracture may happen, the energy or momentum of the power P, acting by means of the lever AB, must be superior to the accumulated energies of the particles. The energy of each depends not only on its cohesive force, but also on its situation; for the supposed insuperable firmness of the rest of the body makes it a lever turning round the fulcrum A, and the cohesion of each particle, such as D or E, acts by means of the arm DA or EA. The energy of each particle will therefore be had by multiplying the force exerted by it in the instant of fracture by the arm of the lever by which it acts.

Let us therefore first suppose, that in the instant of fracture every particle is exerting an equal force f. The energy of D will be $f \times$ DA, and that of E will be $f \times$ EA, and that of the whole will be the sum of all these products. Let the depth DA of the section be called d, and let any undetermined part of it EA be called x, and then the space occupied by any particle will be $\dot{x}$. The cohesion of this space may be represented by $f\dot{x}$, and that of the whole by fd. The energy by which each element $\dot{x}$ of the line DA, or d, resists the fracture, will be $fx\dot{x}$, and the whole accumulated energies will be $f \times \int x\dot{x}$. This we know to be $f \times \frac{1}{2}d^2$, or $fd \times \frac{1}{2}d$. It is the same therefore as if the cohesion fd of the whole section had been acting at the point G, which is the middle of DA.

The reader who is not familiarly acquainted with this fluxionary calculus may arrive at the same conclusion in another way. Suppose the beam, instead of projecting horizontally from a wall, to be hanging from the ceiling, in which it is firmly fixed. Let us consider how the equal cohesion of every part operates in hindering the lower part from separating from the upper by opening round the joint A. The equal cohesion operates just as equal gravity would do, but in the opposite direction. Now we know, by the most elementary mechanics, that the effect of this will be the same as if the whole weight were concentrated in the centre of gravity G of the line DA, and that this point G is in the middle of DA. Now the number of fibres being as the length d of the line, and the cohesion of each fibre being $=f$, the cohesion of the whole line is $f \times d$ or fd.

The accumulated energy therefore of the cohesion in the instant of fracture is $fd \times \frac{1}{2}d$. Now this must be equal or just inferior to the energy of the power employed to break it. Let the length AB be called l; then $P \times l$ is the corresponding energy of the power. This gives us $fd\frac{1}{2}d = pl$ for the equation of equilibrium corresponding to the vertical section ADCB.

Suppose now that the fracture is not permitted at DA, but at another section $\delta\alpha$ more remote from B. The body being prismatic, all the vertical sections are equal; and therefore $fd\frac{1}{2}d$ is the same as before. But the energy of the power is by this means increased, being now $= P \times B\alpha$, instead of $P \times BA$: Hence we see that when the prismatic body is not insuperably strong in all its parts, but equally strong throughout, it must break close at the wall, where the strain or energy of the power is greatest. We see, too, that a power which is just able to break it at the wall is unable to break it anywhere else; also an absolute cohesion fd, which can withstand the power p in the section DA, will not withstand it in the section $\delta\alpha$, and will withstand more in the section $d'a'$.

This teaches us to distinguish between absolute and relative strength. The relative strength of a section has a reference to the strain actually exerted on that section. This relative strength is properly measured by the power which is just able to balance or overcome it, when applied at its proper place. Now since we had $fd\frac{1}{2}d = pl$, we have $p = \frac{fd\frac{1}{2}d}{l}$ for the measure of the strength of the section of the section DA, in relation to the power applied at B.

If the solid is a rectangular beam, whose breadth is b, it is plain that all the vertical sections are equal, and that AG or $\frac{1}{2}d$ is the same in all. Therefore the equa-

Strength of Materials.

tion expressing the equilibrium between the momentum of the external force and the accumulated momenta of cohesion will be $p\,l = f\,d\,b \times \frac{1}{2}d$.

The product $d\,b$ evidently expresses the area of the section of fracture, which we may call s, and we may express the equilibrium thus, $p\,l = f\,s\,\frac{1}{2}d$, and $2\,l : d = f\,s : p$.

Now $f\,s$ is a proper expression of the absolute cohesion of the section of fracture, and p is a proper measure of its strength in relation to a power applied at B. We may therefore say, that *twice the length of a rectangular beam is to the depth as the absolute cohesion to the relative strength.*

Since the action of equable cohesion is similar to the action of equal gravity, it follows, that whatever is the figure of the section, the relative strength will be the same as if the absolute cohesion of all the fibres were acting at the centre of gravity of the section. Let g be the distance between the centre of gravity of the section and the axis of fracture, we shall have $p\,l = f\,s\,g$, and $l : g = f\,s : p$. It will be very useful to recollect this analogy in words: "*The length of a prismatic beam of any shape is to the height of the centre of gravity above the lower side, as the absolute cohesion to the strength relative to this length.*"

Because the relative strength of a rectangular beam is $\frac{f\,b\,d\,\frac{1}{2}d}{l}$ or $\frac{f\,b\,d^2}{2\,l}$, it follows, that the relative strengths of different beams are proportional to the absolute cohesion of the particles, to the breadth, and to the square of the depth directly, and to the length inversely; also in prisms whose sections are similar, the strengths are as the cubes of the diameters.

57 Ascertained on the hypothesis of equal cohesion;

Such are the more general results of the mechanism of this transverse strain, in the hypothesis that all the particles are exerting equal forces in the instant of fracture. We are indebted for this doctrine to the celebrated Galileo; and it was one of the first specimens of the application of mathematics to the science of nature.

We have not included in the preceding investigation that action of the external force by which the solid is drawn sidewise, or tends to slide along the surface of fracture. We have supposed a particle E to be pulled only in the direction E e, perpendicular to the section of fracture, by the action of the crooked lever BAE. But it is also pulled in the direction EA; and its reaction is in some direction ϵ E, compounded of ϵf, by which it resists being pulled outwards; and $\epsilon\,e$ by which it resists being pulled downwards. We are but imperfectly acquainted with the force $\epsilon\,e$, and only know that their accumulated sum is equal to the force p; but in all important cases which occur in practice, it is unnecessary to attend to this force; because it is so small in comparison of the forces in the direction Ee, as we easily conclude from the usual smallness of AD in comparison of AB.

58 but that hypothesis not conformable to nature.

The hypothesis of equal cohesion, exerted by all the particles in the instant of fracture, is not conformable to nature: for we know, that when a force is applied transversely at B, the beam is bent downwards, becoming convex on the upper side; that side is therefore on the stretch. The particles at D are farther removed from each other than those at E, and are therefore *actually exerting* greater cohesive forces. We cannot say with certainty and precision in what proportion each fibre is extended. It seems most probable that the extensions are proportional to the distances from A. We shall suppose this to be really the case. Now recollect the general law which we formerly said was *observed* in all moderate extensions, *viz.* that the attractive forces exerted by the dilated particles were proportional to their dilatations. Suppose now that the beam is so much bent that the particles at D are exerting their utmost force, and that this fibre is just ready to break or actually breaks. It is plain that a total fracture must immediately ensue; because the force which was superior to the full cohesion of the particle at D, and a certain portion of the cohesion of all the rest, will be more than superior to the full cohesion of the particle next within D, and a smaller portion of the cohesion of the remainder.

Now let F represent, as before, the full force of the exterior fibre D, which is exerted by it in the instant of its breaking, and then the force exerted at the same instant by the fibre E will be had by this analogy, AD : AE, or $d : x = f : \frac{f\,x}{d}$, and the force really exerted by the fibre E is $f \times \frac{x}{d}$.

The force exerted by a fibre whose thickness is $\dot{x}$ is therefore $\frac{f\,x\,\dot{x}}{d}$; but this force resists the strain by acting by means of the lever EA or x. Its energy or momentum is therefore $\frac{f\,x^2\,\dot{x}}{d}$, and the accumulated momenta of all the fibres in the line AE will be $f \times$ sum of $\frac{x^2\,\dot{x}}{d}$. This, when x is taken equal to d, will express the momentum of the whole fibres in the line AD. This, therefore, is $f\frac{\frac{1}{3}d^3}{d}$, or $f\,\frac{1}{3}\,d^2$, or $f\,d \times \frac{1}{3}\,d$. Now $f\,d$ expresses the absolute cohesion of the whole line AD. The accumulated momentum is therefore the same as if the absolute cohesion of the whole line were exerted at one-third of AD from A.

From these premises it follows that the equation expressing the equilibrium of the strain and cohesion is $p\,l = f\,d \times \frac{1}{3}\,d$; and hence we deduce the analogy, "*As thrice the length is to the depth, so is the absolute cohesion to the relative strength.*" 59 The strength ascertained on other principles.

This equation and this proportion will equally apply to rectangular beams whose breadth is b; for we shall then have $p\,l = f\,b\,d \times \frac{1}{3}\,d$.

We also see that the relative strength is proportional to the absolute cohesion of the particles, to the breadth, and to the square of the depth directly, and to the length inversely: for p is the measure of the force with which it is resisted, and $p = \frac{f\,b\,d\,\frac{1}{3}\,d}{l}, = \frac{f\,b\,d^2}{3\,l}$. In this respect therefore this hypothesis agrees with the Galilean; but it assigns to every beam a smaller proportion of the absolute cohesion of the section of fracture, in the proportion of three to two. In the Galilean hypothesis this section has a momentum equal to one-half of its absolute strength, but in the other hypothesis it is only one-third. In beams of a different form the proportion may be different.

As this is a most important proposition, and the foundation cation of many practical maxims, we are anxious to have it clearly comprehended, and its evidence perceived by all. Our better informed readers will therefore indulge us while we endeavour to preſent it in another point of view, where it will be better ſeen by thoſe who are not familiarly acquainted with the fluxionary calculus.

60 The ſame propoſition preſented in another point of view. Fig. 6.

Fig. 6. A is a perſpective view of a three-ſided beam projecting horizontally from a wall, and loaded with a weight at B juſt ſufficient to break it. DABC is a vertical plane through its higheſt point D, in the direction of its length. a D a is another vertical ſection perpendicular to AB. The piece being ſuppoſed of inſuperable ſtrength everywhere except in the ſection a D a, and the coheſion being alſo ſuppoſed inſuperable along the line a A a, it can break nowhere but in this ſection, and by turning round a A a as round a hinge. Make D d equal to AD, and let D d repreſent the abſolute coheſion of the fibre at D, which abſolute coheſion we expreſſed by the ſymbol f. Let a plane $a\,d\,a$ be made to paſs through $a\,a$ and d, and let $d\,a'\,a'$ be another croſs ſection. It is plain that the priſmatic ſolid contained between the two ſections a D a and $a'\,d\,a'$ will repreſent the full coheſion of the whole ſection of fracture; for we may conceive this priſm as made up of lines ſuch as Ff, equal and parallel to D d, repreſenting the abſolute coheſion of each particle ſuch as F. The pyramidal ſolid d D $a\,a$, cut off by the plane $d\,a\,a$, will repreſent the coheſions *actually exerted* by the different fibres in the inſtant of fracture. For take any point E in the ſurface of fracture, and draw E e parallel to AB, meeting the plane $a\,d\,a$ in e, and let e AE be a vertical plane. It is evident that D d is to E e as AD to AE; and therefore (ſince the forces exerted by the different fibres are as their extenſion, and their extenſion as their diſtances from the axis of fracture) E e will repreſent the force actually exerted by the fibre in E, while D is exertiṡg its full force D d. In like manner, the plane FFff expreſſes the coheſion exerted by all the fibres in the line FF, and ſo on through the whole ſurface. Therefore the pyramid $d\,a\,a$ D expreſſes the accumulated exertion of the whole ſurface of fracture.

Farther, ſuppoſe the beam to be held perpendicular to the horizon with the end B uppermoſt, and that the weight of the priſm contained between the two ſections a D a and $a'\,d\,a'$ (now horizontal) is juſt able to overcome the full coheſion of the ſection of fracture. The weight of the pyramid d D $a\,a$ will alſo be juſt able to overcome the coheſions *actually exerted* by the different fibres in the inſtant of fracture, becauſe the weight of each fibre, ſuch as E e, is juſt ſuperior to the coheſion actually exerted at E.

Let o be the centre of gravity of the pyramidal ſolid, and draw o O perpendicular to the plane a D a. The whole weight of the ſolid dD $a\,a$ may be conceived as accumulated in the point o, and as acting on the point O, and it will have the ſame tendency to ſeparate the two cohering ſurfaces as when each fibre is hanging by its reſpective point. For this reaſon the point O may be called the *centre of actual effort* of the unequal forces of coheſion. The momentum therefore, or energy by which the cohering ſurfaces are ſeparated, will be properly meaſured by the weight of the ſolid d D $a\,a$ multiplied by OA; and this product is equal to the product of the weight p multiplied by BA, or by l. Thus ſuppoſe that the coheſion along the line AD only is conſidered. The whole coheſion will be repreſented by a triangle AD d. D d repreſents f, and AD is d, and AD is x. Therefore AD d is $\frac{1}{2} f d$. The centre of gravity o of the triangle AD d is in the interſection of a line drawn from A to the middle of D d with a line drawn from d to the middle of AD; and therefore the line o O will make AO$=\frac{2}{3}$ of AD. Therefore the actual momentum of coheſion is $f \times \frac{1}{2} d \times \frac{2}{3} d, = f \times d \times \frac{1}{3} d, = f d \times \frac{1}{3} d$, or equal to the abſolute coheſion acting by means of the lever $\dfrac{d}{3}$. If the ſection of fracture is a rectangle, as in a common joiſt, whoſe breadth $a\,a$ is $= b$, it is plain that all the vertical lines will be repreſented by triangles like AD d; and the whole actual coheſion will be repreſented by a wedge whoſe baſes are vertical planes, and which is equal to half of the parallelopiped AD$\times$D $d \times a\,a$, and will therefore be $= \frac{1}{2} f b d$; and the diſtance AO of its centre of gravity from the horizontal line AA$'$ will be $\frac{2}{3}$ of AD. The momentum of coheſion of a joiſt will therefore be $\frac{1}{2} f b d \times \frac{2}{3} d$, or $f b d \frac{1}{3} d$, as we have determined in the other way.

The beam repreſented in the figure is a triangular priſm. The pyramid D$a\,a\,d$ is $\frac{1}{3}$ of the priſm $a\,a$D$d\,a'a'$. If we make s repreſent the ſurface of the triangle a D a, the pyramid is $\frac{1}{3}$ of $f s$. The diſtance AO of its centre of gravity from the horizontal line AA$'$ is $\frac{1}{2}$ of AD, or $\frac{1}{2} d$. Therefore the momentum of actual coheſion is $\frac{1}{3} f s \times \frac{1}{2} d, = f s \frac{1}{6} d$; that is, it is the ſame as if the full coheſion of all the fibres were accumulated at a point I whoſe diſtance from A is $\frac{1}{6}$th of AD or d; or (that we may ſee its value in every point of view) it is $\frac{1}{6}$th of the momentum of the full coheſion of all the fibres when accumulated at the point D, or acting at the diſtance d=AD.

This is a very convenient way of conceiving the momentum of actual coheſion, by comparing it with the momentum of abſolute coheſion applied at the diſtance AD from the axis of fracture. The momentum of the abſolute coheſion applied at D is to the momentum of actual coheſion in the inſtant of fracture as AD to AI. Therefore the length of AI, or its proportion to AD, is a ſort of index of the ſtrength of the beam. We ſhall call it the Index, and expreſs it by the ſymbol i.

Its value is eaſily obtained. The product of the abſolute coheſion by AI muſt be equal to that of the actual coheſion by AO. Therefore ſay, "as the priſmatic ſolid $a\,a$ D $d\,a'\,a'$ is to the pyramidal ſolid $a\,a$ D d, ſo is AO to AI." We are aſſiſted in this determination by a very convenient circumſtance. In this hypotheſis of the actual coheſions being as the diſtances of the fibres from A, the point O is the centre of oſcillation or percuſſion of the ſurface D $a\,a$ turning round the axis $a\,a$: for the momentum of coheſion of the line FF is FF$\times$F$f\times$EA$=$FF$\times$EA^2, becauſe Ff is equal to EA. Now AO, by the nature of the centre of gravity, is equal to the ſum of all theſe momenta divided by the pyramid $a\,a$ Dd; that is, by the ſum of all the FF$\times$Ff; that is, by the ſum of all the FF$\times$EA.

Therefore $\text{AO}=\dfrac{\text{ſum of FF}\times\text{EA}^2}{\text{ſum of FF}\times\text{EA}}$, which is juſt the value of the diſtance of the centre of percuſſion of the triangle $a\,a$ D from A: (See Rotation). Moreover, if

Strength of Materials.

if G be the centre of gravity of the triangle a D a, we shall have DA to GA as the absolute cohesion to the sum of the cohesions actually exerted in the instant of fracture; for, by the nature of this centre of gravity, AG is equal to $\frac{\text{sum of FF} \times \text{EA}}{\text{sum of FF}}$, and the sum of FF $\times$ AG is equal to the sum of FF $\times$ EA. But the sum of all the lines FF is the triangle a D a, and the sum of all the FF $\times$ EA is the sum of all the rectangles FFff; that is, the pyramid dD $a\,a$. Therefore a prism whose base is the triangle a D a, and whose height is AG, is equal to the pyramid, or will express the sum of the actual cohesions; and a prism, whose base is the same triangle, and whose height is D d or D a, expresses the absolute cohesion. Therefore DA is to GA as the absolute cohesion to the sum of the actual cohesions.

Therefore we have DA : GA = OA : IA.

Therefore, whatever be the form of the beam, that is, whatever be the figure of its section, find the centre of oscillation O, and the centre of gravity G of this section. Call their distances from the axis of fracture o and g. Then AI or $i = \frac{o\,g}{d}$, and the momentum of cohesion is $f s \times \frac{o\,g}{d}$, where s is the area of fracture.

This index is easily determined in all the cases which generally occur in practice. In a rectangular beam AI is $\frac{2}{3}$d of AD; in a cylinder (circular or elliptic) AI is $\frac{5}{8}$ths of AD, &c. &c.

In this hypothesis, that the cohesion actually exerted by each fibre is as its extension, and that the extensions of the fibres are as their distances from A (fig. 5.), it is plain that the forces exerted by the fibres D, E, &c. will be represented by the ordinates Dd, E e, &c. to a straight line A d. And we learn from the principles of ROTATION that the centre of percussion O is in the ordinate which passes through the centre of gravity of the triangle AD d, or (if we consider the whole section having breadth as well as depth) through the centre of gravity of the solid bounded by the planes DA, d A; and we found that this point O was the centre of effort of the cohesions *actually* exerted in the instant of fracture, and that I was the centre of an *equal* momentum, which would be produced if all the fibres were accumulated there and exerted their *full* cohesion.

This consideration enables us to determine, with equal facility and neatness, the strength of a beam in any hypothesis of forces. The above hypothesis was introduced with a cautious limitation to moderate strains, which produced no permanent change of form, or no sett as the artists call it: and this suffices for all purposes of practice, seeing that it would be imprudent to expose materials to more violent strains. But when we compare this theory with experiments in which the pieces are really broken, considerable deviations may be expected, because it is very probable that in the vicinity of rupture the forces are no longer proportional to the extensions.

61 How the relative strength may be determined by any other hypothesis.

That no doubt may remain as to the justness and completeness of the theory, we must show how the relative strength may be determined in any other hypothesis. Therefore suppose that it has been established by experiment on any kind of solid matter, that the forces actually exerted in the instant of fracture by the fibres at D, E, &c. are as the ordinates D d', E e', &c. of any curve line A e' d'. We are supposed to know the form of this curve, and that of the solid which is bounded by the vertical plane through AD, and by the surface which passes through this curve A e' d' perpendicularly to the length of the beam. We know the place of the centre of gravity of this curve surface or solid, and can draw a line through it parallel to AB, and cutting the surface of fracture in some point O. This point is also the centre of effort of all the cohesions actually exerted; and the product of AO and of the solid which expresses the actual cohesions will give the momentum of cohesion equivalent to the former $f s \frac{o\,g}{d}$. Or we may find an index AI, by making AI a fourth proportional to the full cohesion of the surface of fracture, to the accumulated actual cohesions, and to AO; and then $f s \times i$ (=AI) will be the momentum of cohesion; and we shall still have I for the point in which all the fibres may be supposed to exert their full cohesion f, and to produce a momentum of cohesion equal to the real momentum of the cohesions actually exerted, and the relative strength of the beam will still be $p = \frac{f s i}{l}$ or $\frac{f s g o}{d l}$. Thus, if the forces be as the squares of the extensions (still supposed to be as the distances from A), the curve A e' d' will be a common parabola, having AB for its axis and AD for the tangent at its vertex. The area AD d' will be $\frac{1}{3}$d AD $\times$ D d; and in the case of a rectangular beam, AO will be $\frac{3}{4}$ths AD, and AI will be $\frac{1}{4}$th of AD.

We may observe here in general, that if the forces actually exerted in the instant of fracture be as any power q of the distance from A, the index AI will be $= \frac{\text{AD}}{q+2}$ for a rectangular beam, and the momentum of cohesion will always be *(cæteris paribus)* as the breadth and as the square of the depth; nay, this will be the case whenever the action of the fibres D and E is expressed by any *similar functions* of d and x. This is evident to every reader acquainted with the fluxionary calculus.

As far as we can judge from experience, no simple algebraic power of the distance will express the actual cohesions of the fibres. No curve which has either AD or AB for its tangent will suit. The observations which we made in the beginning show, that although the curve of fig. 2. must be sensibly straight in the vicinity of the points of intersection with the axis, in order to agree with our observations which show the moderate extensions to be as the extending forces, the curve *must* be concave towards the axis in all its attractive branches, because it cuts it again. Therefore the curve A e' d' of fig. 5. must make a finite angle with AD or AB, and it must, in all probability, be also concave towards AD in the neighbourhood of d'. It may however be convex in some part of the intermediate arch. We have made experiments on the extensions of different bodies, and find great diversities in this respect: But in all, the moderate extensions were as the forces, and this with great accuracy till the body took a sett, and remained longer than formerly when the extending force was removed.

We must now remark, that this correction of the Galilean hypothesis of equal forces was suggested by the bending

bending which is obſerved in all bodies which are ſtrained tranſverſely. Becauſe they are bent, the fibres on the convex ſide have been extended. We cannot ſay in what proportion this obtains in the different fibres. Our moſt diſtinct notions of the internal equilibrium between the particles render it highly probable that their extenſion is proportional to their diſtance from that fibre which retains its former dimenſions. But by whatever law this is regulated, we ſee plainly that the actions of the ſtretched fibres muſt follow the proportions of ſome function of this diſtance, and that therefore the relative ſtrength of a beam is in all caſes ſuſceptible of mathematical determination.

62 Bernoulli's problem of the elaſtic curve.

We alſo ſee an intimate connection between the ſtrain and the curvature. This ſuggeſted to the celebrated James Bernoulli the problem of the ELASTIC CURVE, i. e. the curve into which an extenſible rigid body will be bent by a tranſverſe ſtrain. His ſolution in the *Acta Lipſiæ* 1694 and 1695 is a very beautiful ſpecimen of mathematical diſcuſſion; and we recommend it to the peruſal of the curious reader, He will find it very perſpicuouſly treated in the firſt volume of his works, publiſhed after his death, where the wide ſteps which he had taken in his inveſtigation are explained ſo as to be eaſily comprehended. His nephew Daniel Bernoulli has given an elegant abridgement in the Peterſburg Memoirs for 1729. The problem is too intricate to be fully diſcuſſed in a work like ours; but it is alſo too intimately connected with our preſent ſubject to be entirely omitted. We muſt content ourſelves with ſhowing the leading mechanical properties of this curve, from which the mathematician may deduce all its geometrical properties.

63 Its leading mechanical property deſcribed.

When a bar of uniform depth and breadth, and of a given length, is bent into an arch of a circle, the extenſion of the outer fibres is proportional to the curvature; for, becauſe the curves formed by the inner and outer ſides of the beam are ſimilar, the circumferences are as the radii, and the radius of the inner circle is to the difference of the radii as the length of the inner circumference is to the difference of the circumferences. The difference of the radii is the depth of the beam, the difference of the circumferences is the extenſion of the outer fibres, and the inner circumference is ſuppoſed to be the primitive length of the beam. Now the ſecond and third quantities of the above analogy, viz. the depth and length of the beam, are conſtant quantities, as is alſo their product. Therefore the product of the inner radius and the extenſion of the outer fibre is alſo a conſtant quantity, and the whole extenſion of the outer fibre is inverſely as the radius of curvature, or is directly as the curvature of the beam.

The mathematical reader will readily ſee, that into whatever curve the elaſtic bar is bent, the whole extenſion of the outer fibre is equal to the length of a ſimilar curve, having the ſame proportion to the thickneſs of the beam that the length of the beam has to the radius of curvature.

Fig. 7.

Now let ADCB (fig. 7.) be ſuch a rod, of uniform breadth and thickneſs, firmly fixed in a vertical poſition, and bent into a curve AEFB by a weight W ſuſpended at B, and of ſuch magnitude that the extremity B has its tangent perpendicular to the action of the weight, or parallel to the horizon. Suppoſe too that the extenſions are proportional to the extending forces. From any two points E and F draw the horizontal ordinates EG, FH. It is evident that the exterior fibres of the ſections E *e* and F *f* are ſtretched by forces which are in the proportion of EG to FH (theſe being the long arms of the levers, and the equal thickneſſes E *e*, F *f* being the ſhort arms). Therefore (by the hypotheſis) their extenſions are in the ſame proportion. But becauſe the extenſions are proportional to ſome ſimilar functions of the diſtance from the axes of fracture E and F, the extenſion of any fibre in the ſection E *e* is to the contemporaneous extenſion of the ſimilarly ſituated fibre in the ſection F *f*, as the extenſion of the exterior fibre in the ſection E *e* is to the extenſion of the exterior fibre in the ſection F *f*: therefore the whole extenſion of E *e* is to the whole extenſion of F *f* as EG to FH, and EG is to FH as the curvature in E to the curvature in F.

Here let it be remarked, that this proportionality of the curvature to the extenſion of the fibres is not limited to the hypotheſis of the proportionality of the extenſions to the extending forces. It follows from the extenſion in the different ſections being as ſome ſimilar function of the diſtance from the axis of fracture; an aſſumption which cannot be refuſed.

This then is the fundamental property of the elaſtic curve, from which its equation, or relation between the abſciſſa and ordinate, may be deduced in the uſual forms, and all its other geometrical properties. Theſe are foreign to our purpoſe; and we ſhall notice only ſuch properties as have an immediate relation to the ſtrain and ſtrength of the different parts of a flexible body, and which in particular ſerve to explain ſome difficulties in the valuable experiments of M. Buffon on the Strength of Beams.

64 It is not a circle.

We obſerve, in the firſt place, that the elaſtic curve cannot be a circle, but is gradually more incurvated as it recedes from the point of application B of the ſtraining forces. At B it has no curvature; and if the bar were extended beyond B there would be no curvature there. In like manner, when a beam is ſupported at the ends and loaded in the middle, the curvature is greateſt in the middle; but at the props, or beyond them, if the beam extend farther, there is no curvature. Therefore when a beam projecting 20 feet from a wall is bent to a certain curvature at the wall by a weight ſuſpended at the end, and a beam of the ſame ſize projecting 20 feet is bent to the very ſame curvature at the wall by a greater weight at 10 feet diſtance, the figure and the mechanical ſtate of the beam in the vicinity of the wall is different in theſe two caſes, though the curvature at the very wall is the ſame in both. In the firſt caſe every part of the beam is incurvated; in the ſecond, all beyond the 10 feet is without curvature. In the firſt experiment the curvature at the diſtance of five feet from the wall is three-fourths of the curvature at the wall; in the ſecond, the curvature at the ſame place is but one-half of that at the wall. This muſt weaken the long beam in this whole interval of five feet, becauſe the greater curvature is the reſult of a greater extenſion of the fibres.

65 Every beam has a certain determinate curvature.

In the next place, we may remark, that there is a certain determinate curvature for every beam which cannot be exceeded without breaking it; for there is a certain ſeparation of two adjoining particles that puts an end to their coheſion. A fibre can therefore

be

Strength of Materials.

be extended only a certain proportion of its length. The ultimate extenſion of the outer fibres muſt bear a certain determinate proportion to its length, and this proportion is the ſame with that of the thickneſs (or what we have hitherto called the depth) to the radius of ultimate curvature, which is therefore determinate.

66
And when of uniform breadth and depth is moſt incurvated where the ſtrain is greateſt.

A beam of uniform breadth and depth is therefore moſt incurvated where the ſtrain is greateſt, and will break in the moſt incurvated part. But by changing its form, ſo as to make the ſtrength of its different ſections in the ratio of the ſtrain, is is evident that the curvature may be the ſame throughout, or may be made to vary according to any law. This is a remark worthy of the attention of the watchmaker. The moſt delicate problem in practical mechanics is ſo to taper the balance-ſpring of a watch that its wide and narrow vibrations may be iſochronous. Hooke's principle *ut tenſio ſic vis* is not ſufficient when we take the *inertia* and motion of the ſpring itſelf into the account. The figure into which it bends and unbends has alſo an influence. Our readers will take notice that the artiſt aims at an accuracy which will not admit an error of $\frac{1}{86400}$th, and that Harriſon and Arnold have actually attained it in ſeveral inſtances. The taper of a ſpring is at preſent a noſtrum in the hands of each artiſt, and he is careful not to impart his ſecret.

Again, ſince the depth of the beam is thus proportional to the radius of ultimate curvature, this ultimate or breaking curvature is inverſely as the depth. It may be expreſſed by $\frac{1}{d}$.

67
To what the curvature is proportional.

When a weight is hung on the end of a priſmatic beam, the curvature is nearly as the weight and the length directly, and as the breadth and the cube of the depth inverſely; for the ſtrength is $= f\frac{b\,d^2}{3\,l}$. Let us ſuppoſe that this produces the ultimate curvature $\frac{1}{d}$. Now let the beam be loaded with a ſmaller weight w, and let the curvature produced be C, we have this analogy $f\frac{b\,d^2}{3\,l} : w = \frac{1}{d} : \mathrm{C}$, and $\mathrm{C} = \frac{3\,l\,w}{f\,b\,d^3}$. It is evident that this is alſo true of a beam ſupported at the ends and loaded between the props; and we ſee how to determine the curvature in its different parts, whether ariſing from the load, or from its own weight, or from both.

When a beam is thus loaded at the end or middle, the loaded point is pulled down, and the ſpace through which it is drawn may be called the DEFLECTION. This

68
Deflection.

may be conſidered as the ſubtenſe of the angle of contact, or as the verſed ſine of the arch into which the beam is bent, and is therefore as the curvature when the length of the arches is given (the flexure being moderate), and as the ſquare of the length of the arch when the curvature is given. The deflection therefore is as the curvature and as the ſquare of the length of the arch jointly; that is, as $\frac{3\,l\,w}{f\,b\,d^3}\times l^2$, or as $\frac{3\,l^3 w}{f\,b\,d^3}$. The deflection from the primitive ſhape is therefore as the bending weight and the cube of the length directly, and as the breadth and cube of the depth inverſely.

In beams juſt ready to break, the curvature is as the depth inverſely, and the deflection is as the ſquare of the length divided by the depth; for the ultimate curvature at the breaking part is the ſame whatever is the length; and in this caſe the deflection is as the ſquare of the length.

69
The theorems reſulting from this ſubject afford the fineſt methods of examining the laws of corpuſcular action.

We have been the more particular in our conſideration of this ſubject, becauſe the reſulting theorems afford us the fineſt methods of examining the laws of corpuſcular action, that is, for diſcovering the variation of the force of coheſion by a change of diſtance. It is true it is not the atomical law, or HYLARCHIC PRINCIPLE as it may juſtly be called, which is thus made acceſſible, but the ſpecific law of the particles of the ſubſtance or kind of matter under examination. But even this is a very great point; and coincidences in this reſpect among the different kinds of matter are of great moment. We may thus learn the nature of the corpuſcular action of different ſubſtances, and perhaps approach to a diſcovery of the *mechaniſm* of chemical affinities. For that chemical actions are inſenſible caſes of local motion is undeniable, and local motion is the province of mechanical diſcuſſion; nay, we ſee that theſe hidden changes are produced by mechanical forces in many important caſes, for we ſee them promoted or prevented by means purely mechanical. The converſion of bodies into elaſtic vapour by heat can at all times be prevented by a *ſufficient* external preſſure. A ſtrong ſolution of Glauber's ſalt will congeal in an inſtant by agitation, giving out its latent heat; and it will remain fluid for ever, and return its latent heat in a cloſe veſſel which it completely fills. Even water will by ſuch treatment freeze in an inſtant by agitation, or remain fluid for ever by confinement. We know that heat is produced or extricated by friction, that certain compounds of gold or ſilver with ſaline matters explode with irreſiſtible violence by the ſmalleſt preſſure or agitation. Such facts ſhould rouſe the mathematical philoſopher, and excite him to follow out the conjectures of the illuſtrious Newton, encouraged by the ingenious attempts of Boſcovich; and the proper beginning of this ſtudy is to attend to the laws of attraction and repulſion exerted by the particles of cohering bodies, diſcoverable by experiments made on their actual extenſions and compreſſions. The experiments of ſimple extenſions and compreſſions are quite inſufficient, becauſe the total ſtretching of a wire is ſo ſmall a quantity, that the miſtake of the 1000th part of an inch occaſions an irregularity which deranges any progreſſion ſo as to make it uſeleſs. But by the bending of bodies, a diſtenſion of $\frac{1}{100}$th of an inch may be eaſily magnified in the deflection of the ſpring ten thouſand times. We know that the inveſtigation is intricate and difficult, but not beyond the reach of our preſent mathematical attainments; and it will give very fine opportunities of employing all the addreſs of analyſis. In the 17th century and the beginning of the 18th this was a ſufficient excitement to the firſt geniuſes of Europe. The cycloid, the catenaria, the elaſtic curve, the velaria, the cauſtics, were reckoned an abundant recompenſe for much ſtudy; and James Bernoulli requeſted, as an honourable monument, that the logarithmic ſpiral might be inſcribed on his tombſtone. The reward for the ſtudy to which we now preſume to incite the mathematicians is the almoſt unlimited extenſion of natural ſcience, important in every particular branch. To go no further than our preſent ſubject, a great deal of important practical knowledge

ledge reſpecting the ſtrength of bodies is derived from the ſingle obſervation, that in the moderate extenſions which happen before the parts are overſtrained the forces are nearly in the proportion of the extenſions or ſeparations of the particles. To return to our ſubject.

70 Bernoulli calls in queſtion this law,

James Bernoulli, in his ſecond diſſertation on the elaſtic curve, calls in queſtion this law, and accommodates his inveſtigation to any hypotheſis concerning the relation of the forces and extenſions. He relates ſome experiments of lute ſtrings where the relation was conſiderably different. Strings of three feet long,

Stretched by	2, 4, 6, 8, 10 pds.
Were lengthened	9, 17, 23, 27, 30 lines.

But this is a moſt exceptionable form of the experiment. The ſtrings were twiſted, and the mechaniſm of the extenſions is here exceedingly complicated, combined with compreſſions and with tranſverſe twiſts, &c. We made experiments on fine ſlips of the gum caoutchouc, and on the juice of the berries of the white bryony, of which a ſingle grain will draw to a thread of two feet long, and again return into a perfectly round ſphere. We meaſured the diameter of the thread by a microſcope with a micrometer, and thus could tell in every ſtate of extenſion the proportional number of particles in the ſections. We found, that though the whole range in which the diſtance of the particles was changed in the proportion of 13 to 1, the extenſions did not *ſenſibly* deviate from the proportion of the forces. The ſame thing was obſerved in the caoutchouc as long as it perfectly recovered its firſt dimenſions. And it is on the authority of theſe experiments that we preſume to announce this as a law of nature.

71 which was firſt aſſumed by Dr Hooke.

Dr Robert Hooke was undoubtedly the firſt who attended to this ſubject, and aſſumed this as a law of nature. Mariotte indeed was the firſt who expreſsly uſed it for determining the ſtrength of beams: this he did about the 1679, correcting the ſimple theory of Galileo. Leibnitz indeed, in his diſſertation in the *Acta Eruditorum* 1684 *de Reſiſtentia Solidorum*, introduces this conſideration, and wiſhes to be conſidered as the diſcoverer; and he is always acknowledged as ſuch by the Bernoullis and others who adhered to his peculiar doctrines. But Marriottè had publiſhed the doctrine in the moſt expreſs terms long before; and Bulfinger, in the *Comment. Petropol.* 1729, completely vindicates his claim. But Hooke was unqueſtionably the diſcoverer of this law. It made the foundation of his theory of ſprings, announced to the Royal Society about the year 1661, and read in 1666. On this occaſion he mentions many things on the ſtrength of bodies as quite familiar to his thoughts, which are immediate deductions from this principle; and among theſe *all* the facts which John Bernoulli ſo vauntingly adduces in ſupport of Leibnitz's finical dogmas about the force of bodies in motion; a doctrine which Hooke might have claimed as his own, had he not perceived its frivolous inanity.

72 Though corrected by Mariotte, it does not properly explain the mechaniſm of tranſverſe ſtrain,

But even with this firſt correction of Marriottè, the mechaniſm of tranſverſe ſtrain is not fully nor juſtly explained. The force acting in the direction BP (fig. 5.), and bending the body ABCD, not only ſtretches the fibres on the ſide oppoſite to the axis of fracture, but compreſſes the ſide AB, which becomes concave by the ſtrain. Indeed it cannot do the one without doing the other: For in order to ſtretch the fibres at D, there muſt be ſome fulcrum, ſome ſupport, on which the virtual lever BAD may preſs, that it may tear aſunder the ſtretched fibres. This fulcrum muſt ſuſtain both the preſſure ariſing from the cohesion of the diſtended fibres, and alſo the action of the external force, which immediately tends to cauſe the prominent part of the beam to ſlide along the ſection DA. Let BAD (fig. 5.) be conſidered as a crooked lever, of which A is the fulcrum. Let an external force be applied at B in the direction BP, and let a force equal to the accumulated coheſion of AD be applied at O in the direction oppoſite to AB, that is, perpendicular to AO; and let theſe two forces be ſuppoſed to balance each other by the intervention of the lever. In the firſt place, the force at O muſt be to the force at B as AB to AO: Therefore, if we make AK equal and oppoſite to AO, and AL equal and oppoſite to AB, the common principles of mechanics inform us that the fulcrum A is affected in the ſame manner as if the two forces AK and AL were immediately applied to it, the force AK being equal to the weight P, and AL equal to the accumulated coheſion actually exerted in the inſtant of fracture. The fulcrum is therefore really preſſed in the direction AM, the diagonal of the parallelogram, and it muſt reſiſt in the direction and with the force MA; and this power of reſiſtance, this ſupport, muſt be furniſhed by the repulſive forces exerted by *thoſe particles only* which are in a ſtate of actual compreſſion. The force AK, which is equal to the external force P, muſt be reſiſted in the direction KA by the lateral coheſion of the whole particles between D and A (the particle D is not only drawn forward but downward). This prevents the part CDAB from ſliding down along the ſection DA.

73 as is fully verified by experiment.

This is fully verified by experiment. If we attempt to break a long ſlip of cork, or any ſuch very compreſſible body, we always obſerve it to bulge out on the concave ſide before it cracks on the other ſide. If it is a body of fibrous or foliated texture, it ſeldom fails ſplintering off on the concave ſide; and in many caſes this ſplintering is very deep, even reaching half way through the piece. In hard and granulated bodies, ſuch as a piece of freeſtone, chalk, dry clay, ſugar, and the like, we generally ſee a conſiderable ſplinter or ſhiver fly off from the hollow ſide. If the fracture be ſlowly made by a force at B gradually augmented, the formation of the ſplinter is very diſtinctly ſeen. It forms a triangular piece like *a* I *b*, which generally breaks in the middle. We doubt not but that attentive obſervation would ſhow that the direction of the crack on each ſide of I is not very different from the direction AM and its correſpondent on the other ſide. This is by no means a circumſtance of idle curioſity, but intimately connected with the mechaniſm of coheſion.

74 Conſequences reſulting from the ſtate of the caſe. Fig. 8.

Let us ſee what conſequences reſult from this ſtate of the caſe reſpecting the ſtrength of bodies. Let DΔKC (fig. 8.) repreſent a vertical ſection of a priſm of compreſſible materials, ſuch as a piece of timber. Suppoſe it loaded with a weight P hung at its extremity. Suppoſe it of ſuch a conſtitution that all the fibres in AD are in a ſtate of dilatation, while thoſe in AΔ are in a ſtate of compreſſion. In the inſtant of fracture the particles at D and E are with-held by forces D *d*, E *e*, and the particles at Δ and E repel, reſiſt, or ſupport, with forces Δ δ, E ε.

Some line, ſuch as *d c* A ε δ, will limit all theſe ordinates,

nates, which repreſent the forces actually exerted in the inſtant of fracture. If the forces be as the extenſions and compreſſions, as we have great reaſon to believe, deA and A$\epsilon\delta$ will be two ſtraight lines. They will form *one* ſtraight line dAδ, if the forces which reſiſt a certain dilatation are equal to the forces which reſiſt an equal compreſſion. But this is quite accidental, and is not ſtrictly true in any body. In moſt bodies which have any conſiderable firmneſs, the compreſſions made by any external force are not ſo great as the dilatations which the ſame force would produce; that is, the repulſions which are excited by any ſuppoſed degree of compreſſion are greater than the attractions excited by the ſame degree of dilatation. Hence it will generally follow, that the angle dAD is leſs than the angle δAΔ, and the ordinates Dd, Ee, &c. are leſs than the correſponding ordinates $\Delta\delta$, Eϵ, &c.

But whatever be the nature of the line dAδ, we are certain of this, that the whole area ADd is equal to the whole area A$\Delta\delta$: for as the force at B is gradually increaſed, and the parts between A and D are more extended, and greater coheſive forces are excited, there is always ſuch a degree of repulſive forces excited in the particles between A and Δ that the one ſet preciſely balances the other. The force at B, acting perpendicularly to AB, has no tendency to puſh the whole piece cloſer on the part next the wall or to pull it away. The ſum of the attractive and repulſive forces actually excited muſt therefore be equal. Theſe ſums are repreſented by the two triangular areas, which are therefore equal.

The greater we ſuppoſe the repulſive forces correſponding to any degree of compreſſion, in compariſon with the attractive forces correſponding to the ſame degree of extenſion, the ſmaller will AΔ be in compariſon of AD. In a piece of cork or ſponge, AΔ may chance to be equal to AD, or even to exceed it; but in a piece of marble, AΔ will perhaps be very ſmall in compariſon of AD.

75
An important conſequence of the compreſſibility of body fully proved.

Now it is evident that the repulſive forces excited between A and Δ have no ſhare in preventing the fracture. They rather contribute to it, by furniſhing a fulcrum to the lever, by whoſe energy the coheſion of the particles in AD is overcome. Hence we ſee an important conſequence of the compreſſibility of the body. Its power of reſiſting this tranſverſe ſtrain is diminiſhed by it, and ſo much the more diminiſhed as the ſtuff is more compreſſible.

This is fully verified by ſome very curious experiments made by Du Hamel. He took 16 bars of willow 2 feet long and $\frac{1}{2}$ an inch ſquare, and ſupporting them by props under the ends, he broke them by weights hung on the middle. He broke 4 of them by weights of 40, 41, 47, and 52 pounds: the mean is 45. He then cut 4 of them $\frac{1}{3}$d through on the upper ſide, and filled up the cut with a thin piece of harder wood ſtuck in pretty tight. Theſe were broken by 48, 54, 50, and 52 pounds; the mean of which is 51. He cut other four $\frac{1}{2}$ through, and they were broken by 47, 49, 50, 46; the mean of which is 48. The remaining four were cut $\frac{2}{3}$ds; and their mean ſtrength was 42.

Another ſet of his experiments is ſtill more remarkable.

Six battens of willow 36 inches long and $1\frac{2}{2}$ ſquare were broken by 525 pounds at a medium.

Six bars were cut $\frac{1}{3}$d through, and the cut filled with a wedge of hard wood ſtuck in with a little force: theſe broke with 551.

Six bars were cut half through, and the cut was filled in the ſame manner: they broke with 542.

Six bars were cut $\frac{3}{4}$ths through: theſe broke with 530.

A batten cut $\frac{3}{4}$ths through, and loaded till nearly broken, was unloaded, and the wedge taken out of the cut. A thicker wedge was put in tight, ſo as to make the batten ſtraight again by filling up the ſpace left by the compreſſion of the wood: this batten broke with 577 pounds.

From this it is plain that more than $\frac{2}{3}$ds of the thickneſs (perhaps nearly $\frac{3}{4}$ths) contributed nothing to the ſtrength.

The point A is the centre of fracture in this caſe; and in order to eſtimate the ſtrength of the piece, we may ſuppoſe that the crooked lever virtually concerned in the ſtrain is DAB. We muſt find the point I, which is the centre of effort of all the attractive forces, or that point where the full coheſion of AD muſt be applied, ſo as to have a momentum equal to the accumulated momenta of all the variable forces. We muſt in like manner find the centre of effort i of the repulſive or ſupporting forces exerted by the fibres lying between A and Δ.

It is plain, and the remark is important, that this laſt centre of effort is the real fulcrum of the lever, although A is the point where there is neither extenſion nor contraction; for the lever is ſupported in the ſame manner as if the repulſions of the whole line AΔ were exerted at that point. Therefore let S repreſent the ſurface of fracture from A to D, and f repreſent the abſolute coheſion of a fibre at D in the inſtant of fracture. We ſhall have $fS \times \overline{I+i} = pl$, or $l : I+i = fS : p$; that is, the length AB is to the diſtance between the two centres of effort I and i, as the abſolute coheſion of the ſection between A and D is to the relative ſtrength of the ſection.

It would be perhaps more accurate to make AI and Ai equal to the diſtances of A from the horizontal lines paſſing through the centres of gravity of the triangles dAD and δAΔ. It is only in this conſtruction that the points I and i are the centres of real effort of the accumulated attractions and repulſions. But I and i, determined as we have done, are the points where the full, equal, actions may be all applied, ſo as to produce the ſame momenta. The final reſults are the ſame in both caſes. The attentive and duly informed reader will ſee that Mr Bulfinger, in a very elaborate diſſertation on the ſtrength of beams in the *Comment. Petropolitan.* 1729, has committed ſeveral miſtakes in his eſtimation of the actions of the fibres. We mention this becauſe his reaſonings are quoted and appealed to as authorities by Muſchenbroek and other authors of note. The ſubject has been conſidered by many authors on the continent. We recommend to the reader's peruſal the very minute diſcuſſions in the Memoirs of the Academy of Paris for 1702 by Varignon, the Memoirs for 1708 by Parent, and particularly that of Coulomb in the *Mem. par les Sçavans Etrangers*, tom. vii.

It is evident from what has been ſaid above, that if S and s repreſent the ſurfaces of the ſections above and below A, and if G and g are the diſtances of their centres of gravity from A, and O and o the diſtances of their

Strength of Materials.

centres of oscillation, and D and d their whole depths, the momentum of cohesion will be $\frac{f S \cdot G \cdot O}{D} = \frac{f s . g . o}{d} = p l$.

If (as is most likely) the forces are proportional to the extensions and compressions, the distances AI and Ai, which are respectively $= \frac{G \cdot O}{D}$ and $\frac{g . o}{d}$, are respectively $= \frac{2}{3}$ DA, and $\frac{2}{3}\, \Delta$ A ; and when taken together are $= \frac{2}{3}$ D Δ. If, moreover, the extensions are equal to the compressions in the instant of fracture, and the body is a rectangular prism like a common joist or beam, then D A and Δ A are also equal; and therefore the momentum of cohesion is $f b \times \frac{1}{2} d \times \frac{1}{3} d, = \frac{f b d^2}{6}, = f b d \times \frac{1}{6} d = p l$. Hence we obtain this analogy, "Six times the length is to the depth as the absolute cohesion of the section is to its relative strength."

76
This consequence farther explained.

Thus we see that the compressibility of bodies has a very great influence on their power of withstanding a transverse strain. We see that in this most favourable supposition of equal dilatations and compressions, the strength is reduced to one half of the value of what it would have been had the body been incompressible. This is by no means obvious; for it does not readily appear how compressibility, which does not diminish the cohesion of a single fibre, should impair the strength of the whole. The reason, however, is sufficiently convincing when pointed out. In the instant of fracture a smaller portion of the section is actually exerting cohesive forces, while a part of it is only serving as a fulcrum to the lever, by whose means the strain on the section is produced. We see too that this diminution of strength does not so much depend on the sensible compressibility, as on its proportion to the dilatability by equal forces. When this proportion is small, A Δ is small in comparison of AD, and a greater portion of the whole fibre is exerting attractive forces. The experiments already mentioned, of Du Hamel de Monceau, on battens of willow, show that its compressibility is nearly equal to its dilatability. But the case is not very different in tempered steel. The famous Harrison, in the delicate experiments which he made while occupied in making his longitude watch, discovered that a rod of tempered steel was nearly as much diminished in its length as it was augmented by the same external force. But it is not by any means certain that this is the proportion of dilatation and compression which obtains in the very instant of fracture. We rather imagine that it is not. The forces are nearly as the dilatations till very near breaking; but we think that they diminish when the body is just going to break. But it seems certain that the forces which resist compression increase faster than the compressions, even before fracture. We know incontestably that the ultimate resistances to compression are insuperable by any force which we can employ. The repulsive forces therefore (in their whole extent) increase faster than the compressions, and are expressed by an assymptotic branch of the Boscovician curve formerly explained. It is therefore probable, especially in the more simple substances, that they increase faster, even in such compressions as frequently obtain in the breaking of hard bodies. We are disposed to think that this is always the case in such bodies as do not fly off in splinters on the concave side; but this must be understood with the exception of the permanent changes which may be made by compression, when the bodies are crippled by it. This always increases the compression itself, and causes the neutral point to shift still more towards D. The effect of this is sometimes very great and fatal.

Experiment alone can help us to discover the proportion between the dilatability and compressibility of bodies. The strain now under consideration seems the best calculated for this research. Thus if we find that a piece of wood an inch square requires 12,000 pounds to tear it asunder by a direct pull, and that 200 pounds will break it transversely by acting 10 inches from the section of fracture, we must conclude that the neutral point A is in the middle of the depth, and that the attractive and repulsive forces are equal. Any notions that we can form of the constitution of such fibrous bodies as timber, make us imagine that the *sensible* compressions, including what arises from the bending up of the compressed fibres, is much greater than the real corpuscular extensions. One may get a general conviction of this unexpected proposition by reflecting on what must happen during the fracture. An undulated fibre can only be drawn straight, and then the corpuscular extension begins; but it may be bent up by compression to any degree, the corpuscular compression being little affected all the while. This observation is very important; and though the forces of corpuscular repulsion may be almost insuperable by any compression that we can employ, a *sensible* compression may be produced by forces not enormous, sufficient to cripple the beam. Of this we shall see very important instances afterwards.

77
The proportional strengths of different pieces follow the same ratio.

It deserves to be noticed, that although the relative strength of a prismatic solid is extremely different in the three hypotheses now considered, yet the proportional strengths of different pieces follow the same ratio; namely, the direct ratio of the breadth, the direct ratio of the square of the depth, and the inverse ratio of the length. In the first hypothesis (of equal forces) the strength of a rectangular beam was $\frac{f b d^2}{2 l}$; in the second (of attractive forces proportioned to the extensions) it was $\frac{f b d^2}{3 l}$; and in the third (equal attractions and repulsions proportional to the extensions and compressions) it was $\frac{f b d^2}{6 l}$, or more generally $\frac{f b d^2}{m l}$, where m expresses the unknown proportion between the attractions and repulsions corresponding to an equal extension and compression.

78
The strength of a piece depends chiefly on its depth.

Hence we derive a piece of useful information, which is confirmed by unexceptionable experience, that the strength of a piece depends chiefly on its depth, that is, on that dimension which is in the direction of the strain. A bar of timber of one inch in breadth and two inches in depth is four times as strong as a bar of only one inch deep, and it is twice as strong as a bar two inches broad and one deep; that is, a joist or lever is always strongest when laid on its edge.

79
And therefore a choice in the manner in which the cohesion is opposed to the strain.

There is therefore a choice in the manner in which the cohesion is opposed to the strain. The general aim must be to put the centre of effort I as far from the fulcrum or the neutral point A as possible, so as to give the greatest energy or momentum to the cohesion. Thus if a triangular bar projecting from a wall is loaded with a weight

Strength of Materials.

weight at its extremity, it will bear thrice as much when one of the ſides is uppermoſt as when it is undermoſt. The bar of fig. 6. would be three times as ſtrong if the ſide AB were uppermoſt and the edge DC undermoſt.

80 The ſtrongeſt joiſt has not the greateſt quantity of timber. Fig. 9.

Hence it follows that the ſtrongeſt joiſt that can be cut out of a round tree is not the one which has the greateſt quantity of timber in it, but ſuch that the product of its breadth by the ſquare of its depth ſhall be the greateſt poſſible. Let ABCD (fig. 9.) be the ſection of this joiſt inſcribed in the circle, AB being the breadth and AD the depth. Since it is a rectangular ſection, the diagonal BD is a diameter of the circle, and BAD is a right-angled triangle. Let BD be called a, and BA be called x; then AD is $=\sqrt{a^2-x^2}$. Now we muſt have $AB \times AD^2$, or $x \times a^2 - x^2$, or $a^2 x - x^3$, a maximum. Its fluxion $a^2\dot{x} - 3x^2\dot{x}$ muſt be made $=0$, or $a^2 = 3x^2$, or $x^2 = \frac{a^2}{3}$. If therefore we make $DE = \frac{1}{3}$ DB, and draw EC perpendicular to BD, it will cut the circumference in the point C, which determines the depth BC and the breadth CD.

Becauſe $BD : BC = CD : CE$, we have the area of the ſection $BC\cdot CD = BD\cdot CE$. Therefore the different ſections having the ſame diagonal BD are proportional to their heights CE. Therefore the ſection BCDA is leſs than the ſection $BcDa$, whoſe four ſides are equal. The joiſt ſo ſhaped, therefore, is both ſtronger, lighter, and cheaper.

81 A hollow tube ſtronger than a ſolid rod containing the ſame quantity of matter, Fig. 10.

The ſtrength of ABCD is to that of a B c D as 10,000 to 9186, and the weight and expence as 10,000 to 10,607; ſo that ABCD is preferable to a B c D in the proportion of 10,607 to 9186, or nearly 115 to 100.

From the ſame principles it follows that a hollow tube is ſtronger than a ſolid rod containing the ſame quantity of matter. Let fig. 10. repreſent the ſection of a cylindric tube, of which AF and BE are the exterior and interior diameters, and C the centre. Draw BD perpendicular to BC, and join DC. Then, becauſe $BD^2 = CD^2 - CB^2$, BD is the radius of a circle containing the ſame quantity of matter with the ring. If we eſtimate the ſtrength by the firſt hypotheſis, it is evident that the ſtrength of the tube will be to that of the ſolid cylinder, whoſe radius is BD, as $BD^2 \times AC$ to $BD^2 \times BD$; that is, as AC to BD: for BD^2 expreſſes the coheſion of the ring or the circle, and AC and BD are equal to the diſtances of the centres of effort (the ſame with the centres of gravity) of the ring and circle from the axis of the fracture.

The proportion of theſe ſtrengths will be different in the other hypotheſes, and is not eaſily expreſſed by a general formula; but in both it is ſtill more in favour of the ring or hollow tube.

The following very ſimple ſolution will be readily underſtood by the intelligent reader. Let O be the centre of oſcillation of the exterior circle, o the centre of oſcillation of the inner circle, and w the centre of oſcillation of the ring included between them. Let M be the quantity of ſurface of the exterior circle, m that of the inner circle, and μ that of the ring.

We have $Fw = \frac{M\cdot FO - m.Fo}{\mu}, = \frac{5FC^2 + EC^2}{4FC}$

and the ſtrength of the ring $= \frac{f\mu \times Fw}{2}$, and the ſtrength of the ſame quantity of matter in the form of a ſolid cylinder is $f\mu \times \frac{5}{8}$ BD; ſo that the ſtrength of the ring is to that of the ſolid rod of equal weight as Fw to $\frac{5}{4}$ BD, or nearly as FC to BD. This will eaſily appear by recollecting that FO is $= \frac{\text{ſum of } p.\,r^2}{m.\,FC}$ (ſee ROTATION), and that the momentum of coheſion is $\frac{fm\cdot FC\cdot Ca}{2FC} = \frac{fm\cdot Fo}{2}$ for the inner circle, &c.

Emerſon has given a very inaccurate approximation to this value in his *Mechanics*, 4to.

82 and more ſtiff.

This property of hollow tubes is accompanied alſo with greater ſtiffneſs; and the ſuperiority in ſtrength and ſtiffneſs is ſo much the greater as the ſurrounding ſhell is thinner in proportion to its diameter.

83 Hence the wiſdom of God in forming the bones, &c. hollow.

Here we ſee the admirable wiſdom of the Author of nature in forming the bones of animal limbs hollow. The bones of the arms and legs have to perform the office of levers, and are thus oppoſed to very great tranſverſe ſtrains. By this form they become incomparably ſtronger and ſtiffer, and give more room for the inſertion of muſcles, while they are lighter and therefore more agile; and the ſame Wiſdom has made uſe of this hollow for other valuable purpoſes of the animal economy. In like manner the quills in the wings of birds acquire by their thinneſs the very great ſtrength which is neceſſary, while they are ſo light as to give ſufficient buoyancy to the animal in the rare medium in which it muſt live and fly about. The ſtalks of many plants, ſuch as all the graſſes, and many reeds, are in like manner hollow, and thus poſſeſs an extraordinary ſtrength. Our beſt engineers now begin to imitate nature by making many parts of their machines hollow, ſuch as their axles of caſt iron, &c.; and the ingenious Mr Ramſden now makes the axes and framings of his great aſtronomical inſtruments in the ſame manner.

In the ſuppoſition of homogeneous texture, it is plain that the fracture happens as ſoon as the particles at D are ſeparated beyond their utmoſt limit of coheſion. This is a determined quantity, and the piece bends till this degree of extenſion is produced in the outermoſt fibre. It follows, that the ſmaller we ſuppoſe the diſtance between A and D, the greater will be the curvature which the beam will acquire before it breaks. Greater depth therefore makes a beam not only ſtronger but alſo ſtiffer. But if the parallel fibres can ſlide on each other, both the ſtrength and the ſtiffneſs will be diminiſhed. Therefore if, inſtead of one beam D Δ KC

Fig. 8. 84 How a ſtrong compound beam may be formed.

(fig. 8.) we ſuppoſe two, D Δ BC and AΔKB, not cohering, each of them will bend, and the extenſion of the fibres AB of the under beam will not hinder the compreſſion of the adjoining fibres AB of the upper beam. The two together therefore will not be more than twice as ſtrong as one of them (ſuppoſing DA = A Δ) inſtead of being four times as ſtrong; and they will bend as much as either of them alone would bend by half the load. This may be prevented, if it were poſſible to unite the two beams all along the ſeam AB, ſo that the one ſhall not ſlide on the other. This may be done in ſmall works, by gluing them together with a cement as ſtrong as the natural lateral coheſion of the fibres. If this cannot be done (as it cannot in large works), the ſliding is prevented by JOGGLING the beams together; that is, by cutting down ſeveral rectangular notches in the upper ſide of the lower beam, and making ſimilar notches

in

Strength of Materials.

in the under ſide of the upper beam, and filling up the ſquare ſpaces with pieces of very hard wood firmly driven in, as repreſented in fig. 11. Some employ iron bolts by way of joggles. But when the joggle is much harder than the wood into which it is driven, it is very apt to work looſe, by widening the hole into which it is lodged. The ſame thing is ſometimes done by ſcarfing the one upon the other, as repreſented in fig. 12.); but this waſtes more timber, and is not ſo ſtrong, becauſe the mutual hooks which this method forms on each beam are very apt to tear each other up. By one or other of theſe methods, or ſomething ſimilar, may a compound beam be formed, of any depth, which will be almoſt as ſtiff and ſtrong as an entire piece.

85
How ſtrength may be combined with pliableneſs.

On the other hand, we may combine ſtrength with pliableneſs, by compoſing our beam of ſeveral thin planks laid on each other, till they make a proper depth, and leaving them at full liberty to ſlide on each other. It is in this manner that coach-ſprings are formed, as is repreſented in fig. 13. In this aſſemblage there muſt be no joggles nor bolts of any kind put through the planks or plates; for this would hinder their mutual ſliding. They muſt be kept together by ſtraps which ſurround them, or by ſomething equivalent.

86
Maxims of conſtruction.

The preceding obſervations ſhow the propriety of ſome maxims of conſtruction, which the artiſts have derived from long experience.

Thus, if a mortiſe is to be cut out of a piece which is expoſed to a croſs ſtrain, it ſhould be cut out from that ſide which becomes concave by the ſtrain, as in fig. 14. but by no means as in fig. 15.

If a piece is to be ſtrengthened by the addition of another, the added piece muſt be joined to the ſide which grows convex by the ſtrain, as in fig. 16. and 17.

Before we go any farther, it will be convenient to recal the reader's attention to the analogy between the ſtrain on a beam projecting from a wall and loaded at the extremity, and a beam ſupported at both ends and loaded in ſome intermediate point. It is ſufficient on this occaſion to read attentively what is delivered in the article ROOF, N° 19.—We learn there that the ſtrain on the middle point C (fig. 17. of the preſent article) of a rectangular beam AB, ſupported on props at A and B, is the ſame as if the part CA projected from a wall, and were loaded with the half of the weight W ſuſpended at A. The momentum of the ſtrain is therefore $\frac{1}{2}W \times \frac{1}{2}AB, = W \times \frac{1}{4}AB = p\,\frac{1}{4}\,l$, or $\frac{p\,l}{4}$. The momentum of coheſion muſt be equal to this in every hypotheſis.

Having now conſidered in ſufficient detal the circumſtances which affect the ſtrength of any ſection of a ſolid body that is ſtrained tranſverſely, it is neceſſary to take notice of ſome of the chief modifications of the ſtrain itſelf. We ſhall conſider only thoſe that occur moſt frequently in our conſtructions.

The ſtrain depends on the external force, and alſo on the lever by which it acts.

87
The ſtrain depends on the external force.

It is evidently of importance, that ſince the ſtrain is exerted in any ſection by means of the coheſion of the parts intervening between the ſection under conſideration and the point of application of the external force, the body muſt be able in all theſe intervening parts to propagate or excite the ſtrain in the remote ſection. In every part it muſt be able to reſiſt the ſtrain excited in that part. It ſhould therefore be equally ſtrong; and it is uſeleſs to have any part ſtronger, becauſe the piece will nevertheleſs break where it is not ſtronger throughout; and it is uſeleſs to make it ſtronger (relatively to its ſtrain) in any part, for it will nevertheleſs equally fail in the part that is too weak.

Suppoſe then, in the firſt place, that the ſtrain ariſes from a weight ſuſpended at one extremity, while the other end is firmly fixed in a wall. Suppoſing alſo the croſs ſections to be all rectangular, there are ſeveral ways of ſhaping the beam ſo that it ſhall be equally ſtrong throughout. Thus it may be equally deep in every part, the upper and under ſurfaces being horizontal planes. The condition will be fulfilled by making all the horizontal ſections triangles, as in fig. 18. The two ſides are vertical planes meeting in an edge at the extremity L. For the equation expreſſing the balance of ſtrain and ſtrength is $p\,l = f\,b\,d^2$. Therefore ſince d^2 is the ſame throughout, and alſo p, we muſt have $fb = l$, and b (the breadth AD of any ſection ABCD) muſt be proportional to l (or AL), which it evidently is.

Or, if the beam be of uniform breadth, we muſt have d^2 everywhere proportional to l. This will be obtained by making the depths the ordinates of a common parabola, of which L is the vertex and the length is the axis. The upper or under ſide may be a ſtraight line, as in fig. 19. or the middle line may be ſtraight, and then both upper and under ſurfaces will be curved. It is almoſt indifferent what is the ſhape of the upper and under ſurfaces, provided the diſtances between them in every part be as the ordinates of a common parabola.

Or, if the ſections are all ſimilar, ſuch as circles, ſquares, or any other ſimilar polygons, we muſt have d^3 or b^3 proportional to l, and the depths or breadths muſt be as the ordinates of a cubical parabola.

88
And on the form of the levers by which it acts.

It is evident that theſe are alſo the proper forms for a lever moveable round a fulcrum, and acted on by a force at the extremity. The force comes in the place of the weight ſuſpended in the caſes already conſidered; and as ſuch levers always are connected with another arm, we readily ſee that both arms ſhould be faſhioned in the ſame manner. Thus in fig. 18. the piece of timber may be ſuppoſed a kind of ſteelyard, moveable round a horizontal axis OP, in the front of the wall, and having the two weights P and π in equilibrio. The ſtrain occaſioned by each at the ſection in which the axis OP is placed muſt be the ſame, and each arm OL and Oλ muſt be equally ſtrong in all its parts. The longitudinal ſections of each arm muſt be a triangle, a common parabola, or a cubic parabola, according to the conditions previouſly given.

And, moreover, all theſe forms are equally ſtrong: For any one of them is equally ſtrong in all its parts, and they are all ſuppoſed to have the ſame ſection at the front of the wall or at the fulcrum. They are not, however, equally ſtiff. The firſt, repreſented in fig. 18. will bend leaſt upon the whole, and the one formed by the cubic parabola will bend moſt. But their curvature at the very fulcrum will be the ſame in all.

It is alſo plain, that if the lever is of the ſecond or third kind, that is, having the fulcrum at one extremity, it muſt ſtill be of the ſame ſhape; for in abſtract mechanics it is indifferent which of the three points is conſidered as the axis of motion. In every lever the two

two forces at the extremities act in one direction, and the force in the middle acts in the oppoſite direction, and the great ſtrain is always at that point. Therefore a lever ſuch as fig. 18. moveable round an axis paſſing horizontally through λ, and acting againſt an obſtacle at OP, is equally able in all its parts to reſiſt the ſtrains excited in thoſe parts.

The ſame principles and the ſame conſtruction will apply to beams, ſuch as joiſts, ſupported at the ends L and λ (fig. 18.), and loaded at ſome intermediate part OP. This will appear evident by merely inverting the directions of the forces at theſe three points, or by recurring to the article Roofs, N° 19.

89
The external ſtraining force may be diſtributed over the beam.

Hitherto we have ſuppoſed the external ſtraining force as acting only in one point of the beam. But it may be uniformly diſtributed all over the beam. To make a beam in ſuch circumſtances equally ſtrong in all its parts, the ſhape muſt be conſiderably different from the former.

90
To make a beam ſtrong which projects from a wall.

Thus ſuppoſe the beam to project from a wall.

If it be of equal breadth throughout, its ſides being vertical planes parallel to each other and to the length, the vertical ſection in the direction of its length muſt be a triangle inſtead of a common parabola; for the weight uniformly diſtributed over the part lying beyond any ſection, is as the length beyond that ſection: and ſince it may all be conceived as collected at its centre of gravity, which is the middle of that length, the lever by which this load acts or ſtrains the ſection is alſo proportional to the ſame length. The ſtrain on the ſection (or momentum of the load) is as the ſquare of that length. The ſection muſt have ſtrength in the ſame proportion. Its ſtrength being as the breadth and the ſquare of the depth, and the breadth being conſtant, the ſquare of the depth of any ſection muſt be as the ſquare of its diſtance from the end, and the depth muſt be as that diſtance; and therefore the longitudinal vertical ſection muſt be a triangle.

But if all the tranſverſe ſections are circles, ſquares, or any other ſimilar figures, the ſtrength of every ſection, or the cube of the diameter, muſt be as the ſquare of the lengths beyond that ſection, or the ſquare of its diſtance from the end; and the ſides of the beam muſt be a ſemicubical parabola.

If the upper and under ſurfaces are horizontal planes, it is evident that the breadth muſt be as the ſquare of the diſtance from the end, and the horizontal ſections may be formed by arches of the common parabola, having the length for their tangent at the vertex.

By recurring to the analogy ſo often quoted between a projecting beam and a joiſt, we may determine the proper form of joiſts which are uniformly loaded through their whole length.

91
The ſtrain upon a beam ſupported at both ends. Fig. 20.

This is a frequent and important caſe, being the office of joiſts, rafters, &c.; and there are ſome circumſtances which muſt be particularly noticed, becauſe they are not ſo obvious, and have been miſunderſtood. When a beam AB (fig. 20.) is ſupported at the ends, and a weight is laid on any point P, a ſtrain is excited in every part of the beam. The load on P cauſes the beam to preſs on A and B, and the props react with forces equal and oppoſite to theſe preſſures. The load at P is to the preſſures at A and B as AB to PB and PA, and the preſſure at A is to that at B as PB to PA; the beam therefore is in the ſame ſtate, with reſpect to ſtrain in every part of it, as if it were reſting on a prop at P, and were loaded at the ends with weights equal to the two preſſures on the props: and obſerve, theſe preſſures are ſuch as will balance each other, being inverſely as their diſtances from P. Let P repreſent the weight or load at P. The preſſure on the prop P muſt be $P \times \frac{PA}{AB}$. This is therefore the reaction of the prop B, and is the weight which we may ſuppoſe ſuſpended at B, when we conceive the beam reſting on a prop at P, and carrying the balancing weights at A and B.

The ſtrain occaſioned at any other point C, by the load P at P, is the ſame with the ſtrain at C, by the weight $P \times \frac{PA}{AB}$ hanging at B, when the beam reſts on P, in the manner now ſuppoſed; and it is the ſame if the beam, inſtead of being balanced on a prop at P, had its part AP fixed in a wall. This is evident. Now we have ſhown at length that the ſtrain at C, by the weight $P \times \frac{PA}{AB}$ hanging at B, is $P \times \frac{PA}{AB} \times BC$. We deſire it to be particularly remarked that the preſſure at A has no influence on the ſtrain at C, ariſing from the action of any load between A and C; for it is indifferent how the part AP of the projecting beam PB is ſupported. The weight at A juſt performs the ſame office with the wall in which we ſuppoſe the beam to be fixed. We are thus particular, becauſe we have ſeen even perſons not unaccuſtomed to diſcuſſions of this kind puzzled in their conceptions of this ſtrain.

Now let the load P be laid on ſome point p between C and B. The ſame reaſoning ſhows us that the point is (with reſpect to ſtrain) in the ſame ſtate as if the beam were fixed in a wall, embracing the part pB, and a weight $= P \times \frac{pB}{AB}$ were hung on at A, and the ſtrain at C is $P \times \frac{pB}{AB} \times AC$.

92
A general propoſition.

In general, therefore, the ſtrain on any point C, ariſing from a load P laid on another point P, is proportional to the rectangle of the diſtances of P and C from the ends neareſt to each. It is $P \times \frac{PA \times CB}{AB}$, or $P \times \frac{pB \times CA}{AB}$, according as the load lies between C and A or between C and B.

Cor. 1. The ſtrains which a load on any point P occaſions on the points C, c, lying on the ſame ſide of P, are as the diſtances of theſe points from the end B. In like manner the ſtrains on E and e are as EA and eA.

Cor. 2. The ſtrain which a load occaſions in the part on which it reſts is as the rectangle of the parts on each ſide. Thus the ſtrain occaſioned at C by a load is to that at D by the ſame load as $AC \times CB$ to $AD \times DB$. It is therefore greateſt in the middle.

93
The ſtrain ariſing from a load diſtributed along the beam.

Let us now conſider the ſtrain on any point C ariſing from a load uniformly diſtributed along the beam. Let AP be repreſented by x, and Pp by $\dot{x}$, and the whole weight on the beam by a. Then

The weight on Pp is . $= a \frac{\dot{x}}{AB}$,

Preſſure

Preſſure on B by the weight on Pp $= a\frac{\dot{x}}{AB} \times \frac{}{AB}$

Or - - - $= a\frac{x\dot{x}}{AB^2}$.

Preſ. on B by whole wt. on AC $= a\frac{\frac{1}{2}AC^2}{AB^2} = a\frac{AC^2}{2AB^2}$.

Strain at C by the weight on AC $= a\frac{AC^2 \times BC}{2\,AB^2}$.

Strain at C by the weight on BC $= a\frac{BC^2 \times AC}{2\,AB^2}$.

Do. by whole weight on AB $= a\frac{AC^2 \times BC + BC^2 \times AC}{2\,AB^2}$,

$= a\frac{AC \times BC \times \overline{AC + CB}}{2\,AB^2}, = a\frac{AC \times BC}{2\,AB}$.

Thus we ſee that the ſtrain is proportional to the rectangle of the parts, in the ſame manner as if the load a had been laid directly on the point C, and is indeed equal to one-half of the ſtrain which would be produced at C by the load a laid on there.

94 Miſtakes in this ſubject committed by authors of reputation.

It was neceſſary to be thus particular, becauſe we ſee in ſome elementary treatiſes of mechanics, publiſhed by authors of reputation, miſtakes which are very plauſible, and miſlead the learner. It is there ſaid, that the preſſure at B from a weight uniformly diffuſed along AB is the ſame as if it were collected at its centre of gravity, which would be the middle of AB; and then the ſtrain at C is ſaid to be this preſſure at B multiplied by BC. But ſurely it is not difficult to ſee the difference of theſe ſtrains. It is plain that the preſſure of gravity downwards on any point between the end A and the point C has no tendency to diminiſh the ſtrain at C, ariſing from the upward reaction of the prop B; whereas the preſſure of gravity between C and B is almoſt in direct oppoſition to it, and muſt diminiſh it. We may however avoid the fluxionary calculus with ſafety by the conſideration of the centre of gravity, by ſuppoſing the weights of AC and BC to be collected at their reſpective centres of gravity; and the reſult of this computation will be the ſame as above: and we may uſe either method, although the weight is not uniformly diſtributed, provided only that we know in what manner it is diſtributed.

This inveſtigation is evidently of importance in the practice of the engineer and architect, informing them what ſupport is neceſſary in the different parts of their conſtructions. We conſidered ſome caſes of this kind in the article ROOFS.

95 To form a joiſt which may have the ſame relative ſtrength in all its parts.

It is now eaſy to form a joiſt, ſo that it ſhall have the ſame relative ſtrength in all its parts.

I. To make it equally able in all its parts to carry a given weight laid on any point C taken at random, or uniformly diffuſed over the whole length, the ſtrength of the ſection at the point C muſt be as AC $\times$ CB. Therefore

1. If the ſides are parallel vertical planes, the ſquare of the depth (which is the only variable dimenſion) or CD^2, muſt be as $AC \times CB$, and the depths muſt be ordinates of an ellipſe.

2. If the tranſverſe ſections are ſimilar, we muſt make CD^3 as $AC \times CB$.

3. If the upper and under ſurfaces are parallel, the breadth muſt be as $AC \times CB$.

II. If the beam is neceſſarily loaded at ſome given point C, and we would have the beam equally able in all its parts to reſiſt the ſtrain ariſing from the weight at C, we muſt make the ſtrength of every tranſverſe ſection between C and either end as its diſtance from that end. Therefore

1. If the ſides are parallel vertical planes, we muſt make $CD^2 : EF^2 = AC : AE$.

2. If the ſections are ſimilar, then $CD^3 : EF^3 = AC : AE$.

3. If the upper and under ſurfaces are parallel, then, breadth at C : breadth at E $= AC : AE$.

96 The ſtrain and ſtrength of ſquare or circular plates of different extent, but of equal thickneſs, may be determined from the ſame principles.

The ſame principles enable us to determine the ſtrain and ſtrength of ſquare or circular plates, of different extent, but equal thickneſs. This may be comprehended in this general propoſition.

Similar plates of equal thickneſs ſupported all round will carry the ſame abſolute weight, uniformly diſtributed, or reſting on ſimilar points, whatever is their extent.

Suppoſe two ſimilar oblong plates of equal thickneſs, and let their lengths and breadths be L, l, and B, b. Let their ſtrength or momentum of coheſion be C, c, and the ſtrains from the weights W, w, be S, s.

Suppoſe the plates ſupported at the ends only, and reſiſting fracture tranſverſely. The ſtrains, being as the weights and lengths, are as WL and $w\,l$, but their coheſions are as the breadths; and ſince they are of equal relative ſtrength, we have $WL : w\,l = B : b$, and $WLb = w\,l\,B$ and $L : l = w\,B : W\,b$: but ſince they are of ſimilar ſhapes $L : l = B : b$, and therefore $w = W$.

The ſame reaſoning holds again when they are alſo ſupported along the ſides, and therefore holds when they are ſupported all round (in which caſe the ſtrength is doubled).

And if the plates are of any other figure, ſuch as circles or ellipſes, we need only conceive ſimilar rectangles inſcribed in them. Theſe are ſupported all around by the continuity of the plates, and therefore will ſuſtain equal weights; and the ſame may be ſaid of the ſegments which lie without them, becauſe the ſtrengths of any ſimilar ſegments are equal, their lengths being as their breadths.

Therefore the thickneſs of the bottoms of veſſels holding heavy liquors or grains ſhould be as their diameters, and as the ſquare root of their depths jointly.

Alſo the weight which a ſquare plate will bear is to that which a bar of the ſame matter and thickneſs will bear as twice the length of the bar to its breadth.

97 The ſtrain of a beam ariſing from its own weight.

There is yet another modification of the ſtrain which tends to break a body tranſverſely, which is of very frequent occurrence, and in ſome caſes muſt be very carefully attended to, viz. the ſtrain ariſing from its own weight.

When a beam projects from a wall, every ſection is ſtrained by the weight of all that projects beyond it. This may be conſidered as all collected at its centre of gravity. Therefore the ſtrain on any ſection is in the joint ratio of the weight of what projects beyond it, and the diſtance of its centre of gravity from the ſection.

The determination of this ſtrain and of the ſtrength neceſſary for withſtanding it muſt be more complicated than the former, becauſe the form of the piece which reſults from this adjuſtment of ſtrain and ſtrength influence.

ences the ſtrain. The general principle muſt evidently be, that the ſtrength or momentum of coheſion of every ſection muſt be as the product of the weight beyond it multiplied by the diſtance of its centre of gravity. For example:

98 General principle reſpecting it. Fig. 21.

Suppoſe the beam DLA (fig. 21.) to project from the wall, and that its ſides are parallel vertical planes, ſo that the depth is the only variable dimenſion. Let $LB = x$ and $Bb = y$. The element $Bbc\,C$ is $= y\dot{x}$. Let G be the centre of gravity of the part lying without Bb, and g be its diſtance from the extremity L. Then $x-g$ is the arm of the lever by which the ſtrain is excited in the ſection Bb. Let Bb or y be as ſome power m of LB; that is, let $y = x^m$. Then the contents of LBb is $\frac{x^{m+1}}{m+1}$. The momentum of gravity round a horizontal axis at L is $yx\dot{x} = x^{m+1}\dot{x}$, and the whole momentum round the axis is $\frac{x^{m+2}}{m+2}$. The diſtance of the centre of gravity from L is had by dividing this momentum by the whole weight which is $\frac{x^{m+1}}{m+1}$. The quotient or g is $\frac{x \times \overline{m+1}}{m+2}$. And the diſtance of the centre of gravity from the ſection Bb is $x - \frac{x \times \overline{m+1}}{m+2}, = \frac{x \times \overline{m+2} - x \times \overline{m+1}}{m+2}, = \frac{x}{m+2}$. Therefore the ſtrain on the ſection Bb is had by multiplying $\frac{x^{m+1}}{m+1}$ by $\frac{x}{m+2}$. The product is $\frac{x^{m+2}}{\overline{m+2} \times \overline{m+1}}$. This muſt be as the ſquare of the depth, or as y^2. But y is as x^m, and y^2 as x^{2m}. Therefore we have $m+2 = 2m$, and $m = 2$; that is, the depth muſt be as the ſquare of the diſtance from the extremity, and the curve $Lb\,A$ is a parabola touching the horizontal line in L.

99 A conoid equally able in every ſection to bear its own weight.

It is eaſy to ſee that a conoid formed by the rotation of this figure round DL will alſo be equally able in every ſection to bear its own weight.

We need not proſecute this farther. When the figure of the piece is given, there is no difficulty in finding the ſtrain; and the circumſtance of equal ſtrength to reſiſt this ſtrain is chiefly a matter of curioſity.

100 The more a beam projects, the leſs able it is to bear its own weight.

It is evident, from what has been already ſaid, that a projecting beam becomes leſs able to bear its own weight, as it projects farther. Whatever may be the ſtrength of the ſection DA, the length may be ſuch that it will break by its own weight. If we ſuppoſe two beams A and B of the ſame ſubſtance and ſimilar ſhapes, that is, having their lengths and diameters in the ſame proportion; and farther ſuppoſe that the ſhorter can juſt bear its own weight; then the longer beam will not be able to do the ſame: For the ſtrengths of the ſections are as the cubes of the diameters, while the ſtrains are as the biquadrates of the diameters; becauſe the weights are as the cubes, and the levers by which theſe weights act in producing the ſtrain are as the lengths or as the diameters.

Theſe conſiderations ſhow us, that in all caſes where ſtrain is affected by the weight of the parts of the machine or ſtructure of any kind, the ſmaller bodies are more able to withſtand it than the greater; and there ſeems to be bounds ſet by nature to the ſize of machines conſtructed of any given materials. Even when the weight of the parts of the machine is not taken into the account, we cannot enlarge them in the ſame proportion in all their parts. Thus a ſteam-engine cannot be doubled in all its parts, ſo as to be ſtill efficient. The preſſure on the piſton is quadrupled. If the lift of the pump be alſo doubled in height while it is doubled in diameter, the load will be increaſed eight times, and will therefore exceed the power. The depth of lift, therefore, muſt remain unchanged; and in this caſe the machine will be of the ſame relative ſtrength as before, independent of its own weight. For the beam being doubled in all its dimenſions, its momentum of coheſion is eight times greater, which is again a balance for a quadruple load acting by a double lever.—But if we now conſider the increaſe of the weight of the machine itſelf, which muſt be ſupported, and which muſt be put in motion by the intervention of its coheſion, we ſee that the large machine is weaker and leſs efficient than the ſmall one.

101 Small bodies more able to withſtan the ſtrain produced by the weight of the machine than great bodies.

There is a ſimilar limit ſet by nature to the ſize of plants and animals formed of the ſame matter. The coheſion of an herb could not ſupport it if it were increaſed to the ſize of a tree, nor could an oak ſupport itſelf if 40 or 50 times bigger, nor could an animal of the make of a long-legged ſpider be increaſed to the ſize of a man; the articulations of its legs could not ſupport it.

102 Even ſmall animals are remarkable for ſtrength and agility.

Hence may be underſtood the prodigious ſuperiority of the ſmall animals both in ſtrength and agility. A man by falling twice his own height may break his firmeſt bones. A mouſe may fall 20 times its height without riſk; and even the tender mite or wood-louſe may fall unhurt from the top of a ſteeple. But their greateſt ſuperiority is in reſpect of nimbleneſs and agility. A flea can leap above 500 times its own length, while the ſtrength of the human muſcles could not raiſe the trunk from the ground on limbs of the ſame conſtruction.

The angular motions of ſmall animals (in which conſiſts their nimbleneſs or agility) muſt be greater than thoſe of large animals, ſuppoſing the force of the muſcular fibre to be the ſame in both. For ſuppoſing them ſimilar, the number of equal fibres will be as the ſquare of their linear dimenſions; and the levers by which they act are as their linear dimenſions. The energy therefore of the moving force is as the cube of theſe dimenſions. But the momentum of inertia, or $\int p.r^2$, is as the 4th power: Therefore the angular velocity of the greater animals is ſmaller. The number of ſtrokes which a fly makes with its wings in a ſecond is aſtoniſhingly great; yet, being voluntary, they are the effects of its agility.

We have hitherto confined our attention to the ſimpleſt form in which this tranſverſe ſtrain can be produced. This was quite ſufficient for ſhowing us the mechaniſm of nature by which the ſtrain is reſiſted; and a very ſlight attention is ſufficient for enabling us to reduce to this every other way in which the ſtrain can be produced. We ſhall not take up the reader's time with the application of the ſame principles to other caſes of this ſtrain, but refer him to what has been ſaid in the article Roofs. In that article we have ſhown the analogy between the ſtrain on the ſection of a beam projecting from a wall and loaded at the extremity, and the ſtrain

Strength of Materials.

strain on the same section of a beam simply resting on supports at the ends, and loaded at some intermediate point or points. The strain on the middle C of a beam AB (fig. 22.) so supported, arising from a weight laid on there, is the same with the strain which half that weight hanging at B would produce on the same section C if the other end of the beam were fixed in a wall. If therefore 1000 pounds hung on the end of a beam projecting 10 feet from a wall will just break it at the wall, it will require 4000 pounds on its middle to break the same beam resting on two props 10 feet asunder. We have also shown in that article the additional strength which will be given to this beam by extending both ends beyond the props, and there framing it firmly into other pillars or supports. We can hardly add any thing to what has been said in that article, except a few observations on the effects of the obliquity of the external force. We have hitherto supposed it to act in the direction BP (fig. 8.) perpendicular to the length of the beam. Suppose it to act in the direction BP′, oblique to BA. In the article Roof we supposed the strain to be the same as if the force p acted at the distance AB′, but still perpendicular to AB: so it is. But the strength of the section A Δ is not the same in both cases; for by the obliquity of the action the piece DCKΔ is pressed to the other. We are not sufficiently acquainted with the corpuscular forces to say precisely what will be the effect of the pressure arising from this obliquity; but we can clearly see, in general, that the point A, which in the instant of fracture is neither stretched nor compressed, must now be farther up, or nearer to D; and therefore the number of particles which are exerting cohesive forces is smaller, and therefore the strength is diminished. Therefore, when we endeavour to proportion the strength of a beam to the strain arising from an external force acting obliquely, we make too liberal allowance by increasing this external force in the ratio of AB to AB. We acknowledge our inability to assign the proper correction. But this circumstance is of very great influence. In many machines, and many framings of carpentry, this oblique action of the straining force is unavoidable; and the most enormous strains to which materials are exposed are generally of this kind. In the frames set up for carrying the ringstones of arches, it is hardly possible to avoid them: for although the judicious engineer disposes his beams so as to sustain only pressures in the direction of their lengths, tending either to crush them or to tear them asunder, it frequently happens that, by the settling of the work, the pieces come to check and bear on each other transversely, tending to break each other across. This we have remarked upon in the article Roofs, with respect to a truss by Mr Price (see Roofs, N° 40, 41, 45). Now when a cross strain is thus combined with an enormous pressure in the direction of the length of the beam, it is in the utmost danger of snapping suddenly across. This is one great cause of the carrying away of masts. They are compressed in the direction of their length by the united force of the shrouds, and in this state the transverse action of the wind soon completes the fracture.

Fig. 22.

103 Effects of the obliquity of the external force.

104 The strain on columns.

When considering the compressing strains to which materials are exposed, we deferred the discussion of the strain on columns, observing that it was not, in the cases which usually occur, a simple compression, but was combined with a transverse strain, arising from the bending of the column. When the column ACB (fig. 23.) resting on the ground at B, and loaded at top with a weight A, acting in the vertical direction AB, is bent into a curve ACB, so that the tangent at C is perpendicular to the horizon, its condition somewhat resembles that of a beam firmly fixed between B and C, and strongly pulled by the end A, so as to bend it between C and A. Although we cannot conceive how a force acting on a straight column AB in the direction AB can bend it, we may suppose that the force acted first in the horizontal direction A b till it was bent to this degree, and that the rope was then gradually removed from the direction A b to the direction AB, increasing the force as much as is necessary for preserving the same quantity of flexure.

Fig. 23.

105 Observations on Euler's theory of the strength of columns.

The first author (we believe) who considered this important subject with scrupulous attention was the celebrated Euler, who published in the Berlin Memoirs for 1757 his Theory of the Strength of Columns. The general proposition established by this theory is, that the strength of prismatical columns is in the direct quadruplicate ratio of their diameters, and the inverse duplicate ratio of their lengths. He prosecuted this subject in the Petersburgh Commentaries for 1778, confirming his former theory. We do not find that any other author has bestowed much attention on it, all seeming to acquiesce in the determinations of Euler, and to consider the subject as of very great difficulty, requiring the application of the most refined mathematics. Muschenbroek has compared the theory with experiment; but the comparison has been very unsatisfactory, the difference from the theory being so enormous as to afford no argument for its justness. But the experiments do not contradict it, for they are so anomalous as to afford no conclusion or general rule whatever.

To say the truth, the theory can be considered in no other light than as a specimen of ingenious and very artful algebraic analysis. Euler was unquestionably the first analyst in Europe for resource and address. He knew this, and enjoyed his superiority, and without scruple admitted any physical assumptions which gave him an opportunity of displaying his skill. The inconsistency of his assumptions with the known laws of mechanism gave him no concern; and when his algebraic processes led him to any conclusion which would make his readers stare, being contrary to all our usual notions, he frankly owned the paradox, but went on in his analysis, saying, "*Sed analysi magis fidendum.*" Mr Robins has given some very risible instances of this confidence in his analysis, or rather of his confidence in the indolent submission of his readers. Nay, so fond was he of this kind of amusement, that after having published an untenable Theory of Light and Colours, he published several Memoirs, explaining the aberration of the heavenly bodies, and deducing some very wonderful consequences, fully confirmed by experience, from the Newtonian principles, which were opposite and totally inconsistent with his own theory, merely because the Newtonian theory gave him "*occasionem analyseos promovendæ.*" We are thus severe in our observations, because his theory of the strength of columns is one of the strongest instances of this wanton kind of proceeding, and because his followers in the Academy of St Petersburgh, such as Mr Fuss, Lexill, and others, adopt his conclusions, and merely echo his words. Since the death of Daniel Bernoulli

Strength of Materials.

Bernoulli no member of that academy has controverted any thing advanced by their *Professor sublimis geometriæ*, to whom they had been indebted for their places and for all their knowledge, having been (most of them) his amanuenses, employed by this wonderful man during his blindness to make his computations and carry on his algebraic investigations. We are not a little surprised to see Mr Emerson, a considerable mathematician, and a man of very independent spirit, hastily adopting the same theory, of which we doubt not but our readers will easily see the falsity.

Fig. 23.

Euler considers the column ACB as in a condition precisely similar to that of an elastic rod bent into the curve by a cord AB connecting its extremities.—In this he is not mistaken.—But he then draws CD perpendicular to AB, and considers the strain on the section C as equal to the momentum or mechanical energy of the weight A acting in the direction DB upon the lever $x\,c$ D, moveable round the fulcrum c, and tending to tear asunder the particles which cohere along the section c C x. This is the same principle (as Euler admits) employed by James Bernoulli in his investigation of the elastic curve ACB. Euler considers the strain on the section $c\,x$ as the same with what it would sustain if the same power acted in the horizontal direction EF on a point E as far removed from C as the point D is. We reasoned in the same manner (as has been observed) in the article Roofs, where the obliquity of action was inconsiderable. But in the present case, this substitution leads to the greatest mistakes, and has rendered the whole of this theory false and useless. It would be just if the column were of materials which are incompressible. But it is evident, by what has been said above, that by the compression of the parts the real fulcrum of the lever shifts away from the point c, so much the more as the compression is greater. In the great compressions of loaded columns, and the almost unmeasurable compressions of the truss beams in the centres of bridges, and other cases of chief importance, the fulcrum is shifted far over towards x, so that very few fibres resist the fracture by their cohesion; and these few have a very feeble energy or momentum, on account of the short arm of the lever by which they act. This is a most important consideration in carpentry, yet makes no element of Euler's theory. The consequence of this is, that a very small degree of curvature is sufficient to cause the column or strutt to snap in an instant, as is well known to every experienced carpenter. The experiment by Muschenbroek, which Euler makes use of in order to obtain a measure of strength in a particular instance, from which he might deduce all others by his theorem, is an incontestable proof of this. The force which broke the column is not the twentieth part of what is necessary for breaking it by acting at E in the direction EF. Euler takes no notice of this immense discrepancy, because it must have caused him to abandon the speculation with which he was then amusing himself.

106
This theory false and useless.

The limits of this work do not afford room to enter minutely upon the refutation of this theory; but we can easily show its uselessness, by its total inconsistency with common observation. It results legitimately from this theory, that if CD have no magnitude, the weight A can have no momentum, and the column cannot be broken —True,—it cannot be broken in this way, snapped by a transverse fracture, if it do not bend; but we know very well that it can be crushed or crippled, and we see this frequently happen. This circumstance or event does not enter into Euler's investigation, and therefore the theory is imperfect at least and useless. Had this crippling been introduced in the form of a physical assumption, every topic of reasoning employed in the process must have been laid aside, as the intelligent reader will easily see. But the theory is not only imperfect, but false. The ordinary reader will be convinced of this by another legitimate consequence of it. Fig 24. is the same with fig. 106. of *Emerson's Mechanics*, where this subject is treated on Euler's principles, and represents a crooked piece of matter resting on the ground at F, and loaded at A with a weight acting in the vertical direction AF. It results from Euler's theory that the strains at b, B, D, E, &c. are as bc, BC, DI, EK, &c. Therefore the strains at G and H are nothing; and this is asserted by Emerson and Euler as a serious truth; and the piece may be thinned *ad infinitum* in these two places, or, even cut through, without any diminution of its strength. The absurdity of this assertion strikes at first hearing. Euler asserts the same thing with respect to a point of contrary flexure. Farther discussion is (we apprehend) needless. Fig. 24.

107
Yet Euler's dissertations deserve a perusal.

This theory must therefore be given up. Yet these dissertations of Euler in the Petersburgh Commentaries deserve a perusal, both as very ingenious specimens of analysis, and because they contain maxims of practice which are important. Although they give an erroneous measure of the comparative strength of columns, they show the immense importance of preventing all bendings, and point out with accuracy where the tendencies to bend are greatest, and how this may be prevented by very small forces, and what a prodigious accession of force this gives the column. There is a valuable paper in the same volume by Fuss *on the Strains on framed Carpentry*, which may also be read with advantage.

108
A new theory cannot be substituted in place of Euler's, till many experiments be made.

It will now be asked, what shall be substituted in place of this erroneous theory? what is the true proportion of the strength of columns? We acknowledge our inability to give a satisfactory answer. Such can be obtained only by a previous knowledge of the proportion between the extensions and compressions produced by equal forces, by the knowledge of the absolute compressions producible by a given force, and by a knowledge of the degree of that derangement of parts which is termed crippling. These circumstances are but imperfectly known to us, and there lies before us a wide field of experimental inquiry. Fortunately the force requisite for crippling a beam is prodigious, and a very small lateral support is sufficient to prevent that bending which puts the beam in imminent danger. A judicious engineer will always employ transverse bridles, as they are called, to stay the middle of long beams, which are employed as pillars, strutts, or truss beams, and are exposed, by their position, to enormous pressures in the direction of their lengths. Such stays may be observed, disposed with great judgement and economy, in the centres employed by Mr Perronet in the erection of his great stone arches. He was obliged to correct this omission made by his ingenious predecessor in the beautiful centres of the bridge of Orleans, which we have no hesitation in affirming to be the finest piece of carpentry in the world.

It

Strength of Materials.

It only remains on this head to compare these theoretical deductions with experiment.

Experiments on the transverse strength of bodies are easily made, and accordingly are very numerous, especially those made on timber, which is the case most common and most interesting. But in this great number of experiments there are very few from which we can draw much practical information. The experiments have in general been made on such small scantlings, that the unavoidable natural inequalities bear too great a proportion to the strength of the whole piece. Accordingly, when we compare the experiments of different authors, we find them differ enormously, and even the experiments by the same author are very anomalous. The completest series that we have yet seen is that detailed by Belidor in his *Science des Ingenieurs*. They are contained in the following table. The pieces were found, even-grained oak. The column b contains the breadths of the pieces in inches; the column d contains their depths; the column l contains their lengths; column p contains the weights (in pounds) which broke them when hung on their middles; and m is the column of averages or mediums.

109 Table of experiments made by Belidor.

N°	b	d	l	p	m	
1	1	1	18	400 415 405	406	The ends lying loose.
2	1	1	18	600 600 624	608	The ends firmly fixed.
3	2	1	18	810 795 812	805	Loose.
4	1	2	18	1570 1580 1590	1580	Loose.
5	1	1	36	185 195 180	187	Loose.
6	1	1	36	285 280 285	283	Fixed.
7	2	2	36	1550 1620 1585	1585	Loose.
8	$2\frac{1}{2}$	$2\frac{1}{2}$	36	1665 1675 1640	1660	Loose.

110 Corollaries deduced from them.

By comparing Experiments 1st and 3d, the strength appears proportional to the breadth.

Experiments 3d and 4th shew the strength proportional to the square of the depth.

Experiments 1st and 5th shew the strength nearly in the inverse proportion of the lengths, but with a sensible deficiency in the longer pieces.

Experiments 5th and 7th shew the strengths proportional to the breadths and the square of the depth.

Experiments 1st and 7th shew the same thing, compounded with the inverse proportion of the length: the deficiency relative to the length is not so remarkable here.

Experiments 1st and 2d, and experiments 5th and 6th shew the increase of strength, by fastening the ends, to be in the proportion of 2 to 3. The theory gives the proportion of 2 to 4. But a difference in the manner of fixing may produce this deviation from the theory, which only supposed them to be held down at places beyond the props, as when a joist is held in the walls, and also rests on two pillars between the walls. (See what is said on this subject in the article Roof, § 19.); where note, that there is a mistake, when it is said that a beam supported at both ends and loaded in the middle, will carry twice as much as if one end were fixed in the wall and the weight suspended at the other end. The reasoning employed there shows that it will carry four times as much.

The chief source of irregularity in such experiments is the fibrous, or rather plated texture of timber. It consists of annual additions, whose cohesion with each other is vastly weaker than that of their own fibres. Let fig. 25. represent the section of a tree, and ABCD, Fig. 25. $a\,b\,c\,d$ the section of two battens that are to be cut out of it for experiment, and let AD and $a\,d$ be the depths, and DC, $d\,c$ the breadths. The batten ABCD will be the strongest, for the same reason that an assemblage of planks set edgewise will form a stronger joist than planks laid above each other like the plates of a coach-spring. M. Buffon found by many trials that the strength of ABCD was to that of $a\,b\,c\,d$ (in oak) nearly as 8 to 7. The authors of the different experiments were not careful that their battens had their plates all disposed similarly with respect to the strain. But even with this precaution they would not have afforded sure grounds of computation for large works; for great beams occupy much, if not the whole, of the section of the tree; and from this it has happened that their strength is less than in proportion to that of a small lath or batten. In short, we can trust no experiments but such as have been made on large beams. These must be very rare, for they are most expensive and laborious, and exceed the abilities of most of those who are disposed to study this matter.

But we are not wholly without such authority. M. Buffon and M. Du Hamel, two of the first philosophers and mechanicians of the age, were directed by government to make experiments on this subject, and were supplied with ample funds and apparatus. The relation of their experiments is to be found in the Memoirs of the French Academy for 1740, 1741, 1742, 1768; as also in Du Hamel's valuable performances *sur l'Exploitation des Arbres, et sur la Conservation et le Transport de Bois*. We earnestly recommend these dissertations to the perusal of our readers, as containing much useful information relative to the strength of timber, and the best methods of employing it. We shall here give an abstract of M. Buffon's experiments.

Strength of Materials.

111
Mr Buffon's experiments on bars of found oak.

He relates a great number which he had profecuted during two years on fmall battens. He found that the odds of a fingle layer, or part of a layer, more or lefs, or even a different difpofition of them, had fuch influence that he was obliged to abandon this method, and to have recourfe to the largeft beams that he was able to break. The following table exhibits one feries of experiments on bars of found oak, clear of knots, and four inches fquare. This is a fpecimen of all the reft.

Column 1ft is the length of the bar in clear feet between the fupports.

Column 2d is the weight of the bar (the 2d day after it was felled) in pounds. Two bars were tried of each length. Each of the firft three pairs confifted of two cuts of the fame tree. The one next the root was always found the heavieft, ftiffeft, and ftrongeft. Indeed M. Buffon fays that this was invariably true, that the heavieft was always the ftrongeft; and he recommends it as certain (or fure) rule for the choice of timber. He finds that this is always the cafe when the timber has grown vigoroufly, forming very thick annual layers. But he alfo obferves that this is only during the advances of the tree to maturity; for the ftrength of the different circles approaches gradually to equality during the tree's healthy growth, and then it decays in thefe parts in a contrary order. Our tool-makers affert the fame thing with refpect to beech: yet a contrary opinion is very prevalent; and wood with a fine, that is, a fmall grain, is frequently preferred. Perhaps no perfon has ever made the trial with fuch minutenefs as M. Buffon, and we think that much deference is due to his opinion.

Column 3d is the number of pounds neceffary for breaking the tree in the courfe of a few minutes.

Column 4th is the inches which it bent down before breaking.

Column 5th is the time at which it broke.

1	2	3	4	5

M. Buffon had found by numerous trials that oak-timber loft much of its ftrength in the courfe of drying or feafoning; and therefore, in order to fecure uniformity, his trees were all felled in the fame feafon of the year, were fquared the day after, and tried the third day. Trying them in this green ftate, gave him an opportunity of obferving a very curious and unaccountable phenomenon. When the weights were laid brifkly on, nearly fufficient to break the log, a very fenfible fmoke was obferved to iffue from the two ends with a fharp hiffing noife. This continued all the while the tree was bending and cracking. This fhows that the log is affected or ftrained through its whole length; indeed this muft be inferred from its bending through its whole length. It alfo fhows us the great effects of the compreffion. It is a pity M. Buffon did not take notice whether this fmoke iffued from the upper or compreffed half of the fection only, or whether it came from the whole. 112

Obfervations on Mr Buffon's experiments.

We muft now make fome obfervations on thefe experiments, in order to compare them with the theory which we have endeavoured to eftablifh.

M. Buffon confiders the experiments with the 5-inch bars as the ftandard of comparifon, having both extended thefe to greater lengths, and having tried more pieces of each length.

Our theory determines the relative ftrength of bars of the fame fection to be inverfely as their lengths. But (if we except the five experiments in the firft column) we find a very great deviation from this rule. Thus the 5-inch bar of 28 feet long fhould have half the ftrength of that of 14 feet, or 2650; whereas it is but 1775. The bar of 14 feet fhould have half the ftrength of that of 7 feet, or 5762; whereas it is but 5300. In like manner, the fourth of 11525 is 2881; but the real ftrength of the 28 feet bar is 1775. We have added a column A, which exhibits the ftrength which each of the 5-inch bars ought to have by the theory. This deviation is moft diftinctly feen in fig. 26. where BK is the fcale of lengths, B being at the point 7 of the fcale, and K at 28. The ordinate CB is $= 11525$, and the other ordinates DE, GK, &c. are refpectively $= \frac{7\,CB}{\text{Length}}$. Fig. 26

The lines DF, GH, &c. are made $= 4350$, 1775, &c. expreffing the ftrengths given by experiment. The 10 feet bar and the 24 feet bar are remarkably anomalous. But all are deficient, and the defect has an evident progreffion from the firft to the laft. The fame thing may be

Strength of Materials.

be shown of the other columns, and even of the first, though it is very small in that column. It may also be observed in the experiments of Belidor, and in all that we have seen. We cannot doubt therefore of its being a law of nature, depending on the true principles of cohesion, and the laws of mechanics.

But it is very puzzling, and we cannot pretend to give a satisfactory explanation of the difficulty. The only effect which we can conceive the length of a beam to have, is to increase the strain at the section of fracture by employing the intervening beam as a lever. But we do not distinctly see what change this can produce in the mode of action of the fibres in this section, so as either to change their cohesion or the place of its centre of effort: yet something of this kind must happen.

We see indeed some circumstances which must contribute to make a smaller weight sufficient, in Mr Buffon's experiments, to break a long beam, than in the exact inverse proportion of its length.

In the first place, the weight of the beam itself augments the strain as much as if half of it were added in form of a weight. Mr Buffon has given the weights of every beam on which he made experiments, which is very nearly 74 pounds per cubic foot. But they are much too small to account for the deviation from the theory. The half weights of the 5-inch beams of 7, 14, and 28 feet length are only 45, 92, and 182 pounds; which makes the real strains in the experiments 11560, 5390, and 1956; which are far from having the proportions of 4, 2, and 1.

Buffon says that healthy trees are universally strongest at the root end; therefore, when we use a longer beam, its middle point, where it is broken in the experiment, is in a weaker part of the tree. But the trials of the 4-inch beams show that the difference from this cause is almost insensible.

The length must have some mechanical influence which the theory we have adopted has not yet explained. It may not however be inadequate to the task. The very ingenious investigation of the elastic curve by James Bernoulli and other celebrated mathematicians is perhaps as refined an application of mathematical analysis as we know. Yet in this investigation it was necessary, in order to avoid almost insuperable difficulties, to take the simplest possible case, viz. where the thickness is exceedingly small in comparison with the length. If the thickness be considerable, the quantities neglected in the calculus are too great to permit the conclusion to be accurate, or very nearly so. Without being able to define the form into which an elastic body of considerable thickness will be bent, we can say with confidence, that in an extreme case, where the compression in the concave side is very great, the curvature differs considerably from the Bernoullian curve. But as our investigation is incomplete and very long, we do not offer it to the reader. The following more familiar considerations will, we apprehend, render it highly probable that the relative strength of beams decreases faster than in the inverse ratio of their length. The curious observation by Mr Buffon of the vapour which issued with a hissing noise from the ends of a beam of green oak, while it was breaking by the load on its middle, shows that the whole length of the piece was affected: indeed it must be, since it is bent throughout. We have shown above, that a certain definite curvature of a beam of a given form is always accompanied by rupture. Now suppose the beam A of 10 feet long, and the beam B of 20 feet long, bent to the same degree, at the place of their fixture in the wall; the weight which hangs on A is nearly double of that which must hang on B. The form of any portion, suppose 5 feet, of these two beams, immediately adjoining to the wall, is considerably different. At the distance of 5 feet the curvature of A is $\frac{1}{2}$ of its curvature at the wall. The curvature of B in the corresponding point is $\frac{3}{4}$ths of the same curvature at the wall. Through the whole of the intermediate 5 feet, therefore, the curvature of B is greater than that of A. This must make it weaker throughout. It must occasion the fibres to slide more on each other (that it may acquire *this* greater curvature), and thus affect their lateral union; and therefore those which are stronger will not assist their weaker neighbours. To this we must add, that in the shorter beams the force with which the fibres are pressed laterally on each other is double. This must impede the mutual sliding of the fibres which we mentioned a little ago; nay, this lateral compression may change the law of longitudinal cohesion (as will readily appear to the reader who is acquainted with Boscovich's doctrines), and increase the strength of the very surface of fracture, in the same way (however inexplicable) as it does in metals when they are hammered or drawn into wire.

113 Probable that the relative strength of beams decreases faster than in the inverse ratio of their length.

The reader must judge how far these remarks are worthy of his attention. The engineer will carefully keep in mind the important fact, that a beam of quadruple length, instead of having $\frac{1}{4}$th of the strength, has only about $\frac{1}{6}$th; and the philosopher should endeavour to discover the cause of this diminution, that he may give the artist a more accurate rule of computation.

114 We cannot discover the precise relation between the curvature and the momentum of cohesion.

Our ignorance of the law by which the cohesion of the particles changes by a change of distance, hinders us from discovering the precise relation between the curvature and the momentum of cohesion; and all we can do is to multiply experiments, upon which we may establish some *empirical* rules for calculating the strength of solids. Those from which we must reason at present are too few and too anomalous to be the foundation of such an empirical formula. We may, however, observe, that Mr Buffon's experiments give us considerable assistance in this particular: For if to each of the numbers of the column for the 5-inch beams, corrected by adding half the weight of the beam, we add the constant number 1245, we shall have a set of numbers which are very nearly reciprocals of the lengths. Let 1245 be called c, and let the weight which is known by experiment to be necessary for breaking the 5-inch beam of the length a be called P. We shall have $\frac{\overline{P+c}\times a}{l}-c=p$. Thus the weight necessary for breaking the 7-foot bar is 11560. This added to 1245, and the sum multiplied by 7, gives $\overline{P+c}\times a=89635$. Let l be 18; then $\frac{89635}{18}-1245=3725,=p$, which differs not more than $\frac{1}{37}$th from what experiment gives us. This rule holds equally well in all the other lengths except the 10 and 24 foot beams, which are very anomalous. Such a formula is abundantly exact for practice, and will answer through a much greater variety of length, though it cannot be admitted as a true one; because, in a certain very great

length,

length, the strength will be nothing. For other sizes the constant number must change in the proportion of d^3, or perhaps of p.

115 Relation between the strength and the square of the depth of the section.

The next comparison which we have to make with the theory is the relation between the strength and the square of the depth of the section. This is made by comparing with each other the numbers in any horizontal line of the table. In making this comparison we find the numbers of the five-inch bars uniformly greater than the rest. We imagine that there is something peculiar to these bars: They are in general heavier than in the proportion of their section, but not so much so as to account for all their superiority. We imagine that this set of experiments, intended as a standard for the rest, has been made at one time, and that the season has had a considerable influence. The fact however is, that if this column be kept out, or uniformly diminished about one-sixteenth in their strength, the different sizes will deviate very little from the ratio of the square of the depth, as determined by theory. There is however a small deficiency in the bigger beams.

We have been thus anxious in the examination of these experiments, because they are the only ones which have been related in sufficient detail, and made on a proper scale for giving us data from which we can deduce confidential maxims for practice. They are so troublesome and expensive that we have little hopes of seeing their number greatly increased; yet surely our navy board would do an unspeakable service to the public by appropriating a fund for such experiments under the management of some man of science.

116 Proportion between the absolute cohesion and the relative strength.

There remains another comparison which is of chief importance, namely, the proportion between the ABSOLUTE COHESION and the RELATIVE STRENGTH. It may be guessed, from the very nature of the thing, that this must be very uncertain. Experiments on the absolute strength must be confined to very small pieces, by reason of the very great forces which are required for tearing them asunder. The values therefore deduced from them must be subject to great inequalities. Unfortunately we have got no detail of any experiments; all that we have to depend on is two passages of Muschenbroek's *Essais de Physique;* in one of which he says that a piece of sound oak $\frac{2}{100}$ths of an inch square is torn asunder by 1150 pounds; and in the other, that an oak plank 12 inches broad and one thick will just suspend 189163 pounds. These give for the cohesion of an inch square 15,755 and 15,763 pounds. Bouguer, in his *Traité du Navire*, says that it is very well known that a rod of sound oak one fourth of an inch square will be torn asunder by 1000 pounds. This gives 16000 for the cohesion of a square inch. We shall take this as a round number, easily used in our computations. Let us compare this with M. Buffon's trials of beams four inches square.

The absolute cohesion of this section is $16,000 \times 16 = 256,000$. Did every fibre exert its whole force in the instant of fracture, the momentum of cohesion would be the same as if it had all acted at the centre of gravity of the section at 2 inches from the axis of fracture, and is therefore 512000. The 4-inch beam, 7 feet long, was broken by 5312 pounds hung on its middle. The half of this, or 2656 pounds, would have broken it, if suspended at its extremity, projecting $3\frac{1}{2}$ feet or 42 inches from a wall. The momentum of this strain is therefore $2656 \times 42, = 111552$. Now this is in equilibrio with the actual momentum of cohesion, which is therefore 111552, instead of 512000. The strength is therefore diminished in the proportion of 512000 to 111552, or very nearly of 4,59 to 1.

As we are quite uncertain as to the place of the centre of effort, it is needless to consider the full cohesion as acting at the centre of gravity, and producing the momentum 512,000; and we may convert the whole into a simple multiplier m of the length, and say, *as* m *times the length is to the depth, so is the absolute cohesion of the section to the relative strength.* Therefore let the absolute cohesion of a square inch be called f, the breadth b, the depth d, and the length l (all in inches), the relative strength, or the external force p, which balances it, is $\frac{f b d^2}{9,18 l}$, or in round numbers $\frac{f b d^2}{9 l}$; for $m = 2 \times 4,59$.

This great diminution of strength cannot be wholly accounted for by the inequality of the cohesive forces exerted in the instant of fracture; for in this case we know that the centre of effort is at $\frac{1}{3}$d of the height in a rectangular section (because the forces really exerted are as the extensions of the fibres). The relative strength would be $\frac{f b d^2}{3 l}$, and p would have been 8127 instead of 2656.

We must ascribe this diminution (which is three times greater than that produced by the inequality of the cohesive forces) to the compression of the under part of the beam; and we must endeavour to explain in what manner this compression produces an effect which seems so little explicable by such means.

As we have repeatedly observed, it is a matter of nearly universal experience that the forces *actually* exerted by the particles of bodies, when stretched or compressed, are very nearly in the proportion of the distances to which the particles are drawn from their natural positions. Now, although we are certain that, in enormous compressions, the forces increase faster than in this proportion, this makes no sensible change in the present question, because the body is broken before the compressions have gone so far; nay, we imagine that the compressed parts are crippled in most cases even before the extended parts are torn asunder. Muschenbroek asserts this with great confidence with respect to oak, on the authority of his own experiments. He says, that although oak will suspend half as much again as fir, it will not support, as a pillar, two-thirds of the load which fir will support in that form.

We imagine therefore that the mechanism in the *present* case is nearly as follows:

Let the beam DCKΔ (fig. 27.) be loaded at its extremity with the weight P, acting in the direction KP perpendicular to DC. Let DΔ be the section of fracture. Let DA be about one-third of DΔ. A will be the particle or fibre which is neither extended nor compressed. Make $\Delta \delta : D d = DA : A\Delta$. The triangles DAd, $\Delta A \delta$, will represent the accumulated attracting and repelling forces. Make AI and $A i = \frac{1}{3}$DA and $\frac{1}{3} \Delta A$. The point I will be that to which the full cohesion Dd or f of the particles in AD must be applied, so as to produce the same momentum which the variable forces at I, D, &c. really produce at their several points Fig. 27.

of

of application. In like manner, i is the centre of similar effort of the repulsive forces excited by the compression between A and Δ, and it is the real fulcrum of a bended lever I i K, by which the whole effect is produced. The effect is the same as if the full cohesion of the stretched fibres in AD were accumulated in I, and the full repulsion of all the compressed fibres in A Δ were accumulated in i. The forces which are balanced in the operation are the weight P, acting by the arm k i, and the full cohesion of AD acting by the arm I i. The forces exerted by the compressed fibres between A and Δ only serve to give support to the lever, that it may exert its strain.

We imagine that this does not differ much from the real procedure of nature. The position of the point A may be different from what we have deduced from Mr Buffon's experiments, compared with Muschenbroek's value of the absolute cohesion of a square inch. If this last should be only 12000, DA must be greater than we have here made it, in the proportion of 12000 to 16000. For I i must still be made $=\frac{2}{3}$ A Δ, supposing the forces to be proportional to the extensions and compressions. There can be no doubt that a part only of the cohesion of D Δ operates in resisting the fracture in all substances which have any compressibility; and it is confirmed by the experiments of Mr Du Hamel on willow, and the inferences are by no means confined to that species of timber. We say therefore, that when the beam is broken, the cohesion of AD alone is exerted, and that each fibre exerts a force proportional to its extension; and the accumulated momentum is the same as if the full cohesion of AD were acting by the lever I i $=\frac{1}{3}$d of D Δ.

It may be said, that if only one-third of the cohesion of oak be exerted, it may be cut two-thirds through without weakening it. But this cannot be, because the cohesion of the whole is employed in preventing the lateral slide so often mentioned. We have no experiments to determine that it *may not* be cut through one-third without loss of its strength.

This must not be considered as a subject of mere speculative curiosity. It is intimately connected with all the practical uses which we can make of this knowledge; for it is almost the only way that we can learn the compressibility of timber. Experiments on the direct cohesion are indeed difficult, and exceedingly expensive if we attempt them in large pieces. But experiments on compression are almost impracticable. The most instructive experiments would be, first to establish, by a great number of trials, the transverse force of a modern batten; and then to make a great number of trials of the diminution of its strength, by cutting it through on the concave side. This would very nearly give us the proportion of the cohesion which really operates in resisting fractures. Thus if it be found that one-half of the beam may be cut on the under side without diminution of its strength (taking care to drive in a slice of harder wood), we may conclude that the point A is at the middle, or somewhat above it.

Much lies before the curious mechanician, and we are as yet very far from a scientific knowledge of the strength of timber.

In the mean time, we may derive from these experiments of Buffon a very useful practical rule, without relying on any value of the absolute cohesion of oak. We see that the strength is nearly as the breadth, as the square of the depth, and as the inverse of the length. It is most convenient to measure the breadth and depth of the beam in inches, and its length in feet. Since, then, a beam four inches square and seven feet between the supports is broken by 5312 pounds, we must conclude that a batten one inch square and one foot between the supports will be broken by 581 pounds. Then the strength of any other beam of oak, or the weight which will just break it when hung on its middle, is $581\frac{b\,d^2}{l}$.

117 A useful practical rule may be deduced from Mr Buffon's experiments.

But we have seen that there is a very considerable deviation from the inverse proportion of the lengths, and we must endeavour to accommodate our rule to this deviation. We found, that by adding 1245 to each of the ordinates or numbers in the column of the five-inch bars, we had a set of numbers very nearly reciprocal of the lengths; and if we make a similar addition to the other columns in the proportion of the cubes of the sixes, we have nearly the same result. The greatest error (except in the case of experiments which are very irregular) does not exceed $\frac{1}{15}$th of the whole. Therefore, for a radical number, add to the 5312 the number 640, which is to 1245 very nearly as 4^3 to 5^3. This gives 5952. The 64th of this is 93, which corresponds to a bar of one inch square and seven feet long. Therefore 93×7 will be the reciprocal corresponding to a bar of one foot. This is 651. Take from this the present empirical correction, which is $\frac{b\,40}{b\,4}$, or 10, and there remains 641 for the strength of the bar. This gives us for a general rule $p=651\frac{b\,d^2}{l}-10\,b\,d^2$.

Example. Required the weight necessary to break an oak beam eight inches square and 20 feet between the props, $p=651\times\frac{8\times 8^2}{20}-10\times 8\times 8^2$. This is 11545, whereas the experiment gives 11487. The error is very small indeed. The rule is most deficient in comparison with the five-inch bars, which we have already said appear stronger than the rest.

The following process is easily remembered by such as are not algebraists.

Multiply the breadth in inches twice by the depth, and call this product f. Multiply f by 651, and divide by the length in feet. From the quotient take 10 times f. The remainder is the number of pounds which will break the beam.

We are not sufficiently sensible of our principles to be confident that the correction $10\,f$ should be in the proportion of the section, although we think it most probable. It is quite empirical, founded on Buffon's experiments. Therefore the safe way of using this rule is to suppose the beam square, by increasing or diminishing its breadth till equal to the depth. Then find the strength by this rule, and diminish or increase it for the change which has been made in its breadth. Thus, there can be no doubt that the strength of the beam given as an example is double of that of a beam of the same depth and half the breadth.

The reader cannot but observe that all this calculation relates to the very greatest weight which a beam will bear for a very few minutes. Mr Buffon uniformly found

found that two-thirds of this weight ſenſibly impaired its ſtrength, and frequently broke it at the end of two or three months. One-half of this weight brought the beam to a certain bend, which did not increaſe after the firſt minute or two, and may be borne by the beam for any length of time. But the beam contracted a bend, of which it did not recover any conſiderable portion. One-third ſeemed to have no permanent effect on the beam; but it recovered its rectilineal ſhape completely, even after having been loaded ſeveral months, provided that the timber was ſeaſoned when firſt loaded; that is to ſay, one-third of the weight which would quickly break a ſeaſoned beam, or one-fourth of what would break one juſt felled, may lie on it for ever without giving the beam a ſett.

We have no detail of experiments on the ſtrength of other kinds of timber: only Mr Buffon ſays, that fir has about $\frac{6}{10}$ths of the ſtrength of oak; Mr Parent makes it $\frac{1}{1}\frac{0}{1}$ths; Emerſon, $\frac{2}{3}$ds, &c.

We have been thus minute in our examination of the mechaniſm of this tranſverſe ſtrain, becauſe it is the greateſt to which the parts of our machines are expoſed. We wiſh to impreſs on the minds of artiſts the neceſſity of avoiding this as much as poſſible. They are improving in this reſpect, as may be ſeen by comparing the centres on which ſtone arches of great ſpan are now turned with thoſe of former times. They were formerly a load of mere joiſts reſting on a multitude of poſts, which obſtructed the navigation, and were frequently loſing their ſhape by ſome of the poſts ſinking into the ground. Now they are more generally truſſes, where the beams abutt on each other, and are relieved from tranſverſe ſtrains. But many performances of eminent artiſts are ſtill very injudiciouſly expoſed to croſs ſtrains. We may inſtance one which is conſidered as a fine work, viz. the bridge at Walton on Thames. Here every beam of the great arch is a joiſt, and it hangs together by framing. The fineſt piece of carpentry that we have ſeen is the centre employed in turning the arches of the bridge at Orleans, deſcribed by Perronet. In the whole there is not one croſs ſtrain. The beam, too, of Hornblower's ſteam-engine, deſcribed in that article, is very ſcientifically conſtructed.

118
Strain produced by twiſting.

IV. The laſt ſpecies of ſtrain which we are to examine is that produced by twiſting. This takes place in all axles which connect the working parts of machines.

119
The reſiſtance muſt be proportional to the number of particles.

Although we cannot pretend to have a very diſtinct conception of that modification of the coheſion of a body by which it reſiſts this kind of ſtrain, we can have no doubt that, when all the particles act alike, the reſiſtance muſt be proportional to the number. Therefore if we ſuppoſe the two parts ABCD, ABFE (fig. 28.), of the body EFCD to be of inſuperable ſtrength, but cohering more weakly in the common ſurface AB, and that one part ABCD is puſhed laterally in the direction AB, there can be no doubt that it will yield only there, and that the reſiſtance will be proportional to the ſurface.

Fig. 28.

In like manner, we can conceive a thin cylindrical tube, of which KAH (fig. 29) is the ſection, as cohering more weakly in that ſection than anywhere elſe. Suppoſe it to be graſped in both hands, and the two parts twiſted round the axis in oppoſite directions, as we would twiſt the two joints of a flute, it is plain that it will firſt fail in this ſection, which is the circumference of a circle, and the particles of the two parts which are contiguous to this circumference will be drawn from each other laterally. The total reſiſtance will be as the number of equally reſiſting particles, that is, as the circumference (for the tube being ſuppoſed very thin, there can be no ſenſible difference between the dilatation of the external and internal particles). We can now ſuppoſe another tube within this, and a third within the ſecond, and ſo on till we reach the centre. If the particles of each ring exerted the ſame force (by ſuffering the ſame dilatation in the direction of the circumference), the reſiſtance of each ring of the ſection would be as its circumference and its breadth (ſuppoſed indefinitely ſmall, and the whole reſiſtance would be as the ſurface; and this would repreſent the reſiſtance of a ſolid cylinder. But when a cylinder is twiſted in this manner by an external force applied to its circumference, the external parts will ſuffer a greater circular extenſion than the internal; and it appears that this extenſion (like the extenſion of a beam ſtrained tranſverſely) will be proportional to the diſtance of the particles from the axis. We cannot ſay that this is demonſtrable, but we can aſſign no proportion that is more probable. This being the caſe, the forces ſimultaneouſly exerted by each particle will be as its diſtance from the axis. Therefore the whole force exerted by each ring will be as the ſquare of its radius, and the accumulated force actually exerted will be as the cube of the radius; that is, the accumulated force exerted by the whole cylinder, whoſe radius is CA, is to the accumulated force exerted *at the ſame time* by the part whoſe radius is CE, as CA^3 to CE^3.

Fig. 29.

The whole coheſion now exerted is juſt two-thirds of what it would be if all the particles were exerting the ſame attractive forces which are juſt now exerted by the particles in the external circumference. This is plain to any perſon in the leaſt familiar with the fluxionary calculus. But ſuch as are not may eaſily ſee it in this way.

Let the rectangle AC ca be ſet upright on the ſurface of the circle along the line CA, and revolve round the axis Cc. It will generate a cylinder whoſe height is Cc or Aa, and having the circle KAH for its baſe. If the diagonal Ca be ſuppoſed alſo to revolve, it is plain that the triangle cCa will generate a cone of the ſame height, and having for its baſe the circle deſcribed by the revolution of ca, and the point C for its apex. The cylindrical ſurface generated by Aa will expreſs the whole coheſion exerted by the circumference AHK, and the cylindrical ſurface generated by Ee will repreſent the coheſion exerted by the circumference ELM, and the ſolid generated by the triangle CAa will repreſent the coheſion exerted by the whole circle AHK, and the cylinder generated by the rectangle ACca will repreſent the coheſion exerted by the ſame ſurface if each particle had ſuffered the extenſion Aa.

Now it is plain, in the firſt place, that the ſolid generated by the triangle eEC is to that generated by aAC as EC^3 to AC^3. In the next place, the ſolid generated by aAC is two-thirds of the cylinder, becauſe the cone generated by cCa is one-third of it.

We may now ſuppoſe the cylinder twiſted till the particles in the external circumference loſe their coheſion. There can be no doubt that it will now be wrenched aſunder, all the inner circles yielding in ſucceſſion. Thus we obtain one uſeful information, viz. that a body of homogeneous texture reſiſts a *ſimple twiſt* with two-thirds

Strength of Materials.

thirds of the force with which it resists an attempt to force one part laterally from the other, or with one-third part of the force which will cut it asunder by a square-edged tool. For to drive a square-edged tool through a piece of lead, for instance, is the same as forcing a piece of the lead as thick as the tool laterally away from the two pieces on each side of the tool. Experiments of this kind do not seem difficult, and they would give us very useful information.

120 With what force a body of a homogeneous texture resists a simple twist.

121 The forces exerted in breaking two cylinders are as the squares of the diameters.

When two cylinders AHK and BNO are wrenched asunder, we must conclude that the external particles of each are just put beyond their limits of cohesion, are equally extended, and are exerting equal forces. Hence it follows, that in the instant of fracture the sum total of the forces actually exerted are as the squares of the diameters.

For drawing the diagonal C e, it is plain that E e, $=$ A a, expresses the distension of the circumference ELM, and that the solid generated by the triangle CE e expresses the cohesion exerted by the surface of the circle ELM, when the particles in the circumference suffer the extension E e equal to A a. Now the solids generated by CA a and CE e being respectively two-thirds of the corresponding cylinders, are as the squares of the diameters.

122 Relative strength of the section to the external force employed to break it.

Having thus ascertained the real strength of the section, and its relation to its absolute lateral strength, let us examine its strength relative to the external force employed to break it. This examination is very simple in the case under consideration. The straining force must act by some lever, and the cohesion must oppose it by acting on some other lever. The centre of the section may be the neutral point, whose position is not disturbed.

Let F be the force exerted laterally by an exterior particle. Let a be the radius of the cylinder, and x the indeterminate distance of any circumference, and $\dot{x}$ the indefinitely small interval between the concentric arches; that is, let $\dot{x}$ be the breath of a ring and x its radius. The forces being as the extensions, and the extensions as the distances from the axis, the cohesion actually exerted at any part of any ring will be $f\frac{x\dot{x}}{a}$. The force exerted by the whole ring (being as the circumference or as the radius) will be $f\frac{x^2\dot{x}}{a}$. The momentum of cohesion of a ring, being as the force multiplied by its lever, will be $f\frac{x^3\dot{x}}{a}$. The accumulated momentum will be the sum or fluent of $f\frac{x^3\dot{x}}{a}$; that is, when $x=a$, it will be $\frac{1}{4}f\frac{a^4}{a}, = \frac{1}{4}fa^3$.

123 The resistance of the axle is as the cube of its diameter.

Hence we learn that the strength of an axle, by which it resists being wrenched asunder by a force acting at a given distance from the axis, is as the cube of its diameter.

But farther, $\frac{1}{4}fa^3$ is $=fa^2\times\frac{1}{4}a$. Now fa^2 represents the full lateral cohesion of the section. The momentum therefore is the same as if the full lateral cohesion were accumulated at a point distant from the axis by one-fourth of the radius or one-eighth of the diameter of the cylinder.

Strength of Materials.

Therefore let F be the number of pounds which measures the lateral cohesion of a circular inch, d the diameter of the cylinder in inches, and l the length of the lever by which the straining force p is supposed to act, we shall have $F\times\frac{1}{8}d^3=pl$, and $F\frac{d^3}{8l}=p$.

We see in general that the strength of an axle, by which it resists being wrenched asunder by twisting, is as the cube of its diameter.

We see also that the internal parts are not acting so powerfully as the external. If a hole be bored out of the axle of half its diameter, the strength is diminished only one-eighth, while the quantity of matter is diminished one-fourth. Therefore hollow axles are stronger than solid ones containing the same quantity of matter. Thus let the diameter be 5 and that of the hollow 4: then the diameter of another solid cylinder having the same quantity of matter with the tube is 3. The strength of the solid cylinder of the diameter 5 may be expressed by 5^3 or 125. Of this the internal part (of the diameter 4) exerts 64; therefore the strength of the tube is $125-64, = 61$. But the strength of the solid axle of the same quantity of matter and diameter 3 is 3^3, or 27, which is not half of that of the tube.

114 Hollow axles more proper than solid ones,

125 and now generally used.

Engineers, therefore, have of late introduced this improvement in their machines, and the axles of cast iron are all made hollow when their size will admit it. They have the additional advantage of being much stiffer, and of affording much better fixture for the flanches, which are used for connecting them with the wheels or levers by which they are turned and strained. The superiority of strength of hollow tubes over solid cylinders is much greater in this kind of strain than in the former or transverse. In this last case the strength of this tube would be to that of the solid cylinder of equal weight as 61 to 32 and a half nearly.

The apparatus which we mentioned on a former occasion for trying the lateral strength of a square inch of solid matter, enabled us to try this theory of twist with all desirable accuracy. The bar which hung down from the pin in the former trials was now placed in a horizontal position, and loaded with a weight at the extremity. Thus it acted as a powerful lever, and enabled us to wrench asunder specimens of the strongest materials. We found the results perfectly conformable to the theory, in as far as it determined the proportional strength of different sizes and forms: but we found the ratio of the resistance to twisting to the simple lateral resistance considerably different; and it was some time before we discovered the cause.

126 The ratio of resistance to twisting to the simple lateral resistance appears different.

We had here taken the simplest view that is possible of the action of cohesion in resisting a twist. It is frequently exerted in a very different way. When, for instance, an iron axle is joined to a wooden one by being driven into one end of it, the extensions of the different circles of particles are in a very different proportion. A little consideration will show that the particles in immediate contact with the iron axle are in a state of violent extension; so are the particles of the exterior surface of the wooden part, and the intermediate parts are less strained. It is almost impossible to assign the exact proportion of the cohesive forces exerted in the different parts.

Strength of Materials.

parts. Numberlefs cafes can be pointed out where parts of the axle are in a ftate of compreffion, and where it is ftill more difficult to determine the ftate of the other particles. We muft content ourfelves with the deductions made from this fimple cafe, which is fortunately the moft common. In the experiments juft now mentioned the centre of the circle is by no means the neutral point, and it is very difficult to afcertain its place: but when this confideration occurred to us, we eafily freed the experiments from this uncertainty, by extending the lever to both fides, and by means of a pulley applied equal force to each arm, acting in oppofite directions. Thus the centre became the neutral point, and the refiftance to twift was found to be two-thirds of the fimple lateral ftrength.

127 But when the experiment was altered, it was exactly the fame.

128 Experiments on chalk, clay, and wax, fatisfactory; but thofe on timber irregular.

We beg leave to mention here that our fuccefs in thefe experiments encouraged us to extend them much farther. We hoped by thefe means to difcover the abfolute cohefion of many fubftances, which would have required an enormous apparatus and a moft unmanageable force to tear them afunder directly. But we could reafon with confidence from the refiftance to twift (which we could eafily meafure), provided that we could afcertain the proportion of the direct and the lateral ftrengths. Our experiments on chalk, finely prepared clay, and white bees-wax (of one melting and one temperature), were very confiftent and fatisfactory. But we have hitherto found great irregularities in this proportion in bodies of a fibrous texture like timber. Thefe are the moft important cafes, and we ftill hope to be able to accomplifh our project, and to give the public fome valuable information. This being our fole object, it was our duty to mention the method which promifes fuccefs, and thus excite others to the tafk; and it will be no mortification to us to be deprived of the honour of being the firft who thus adds to the ftock of experimental knowledge.

When the matter of the axle is of the moft fimple texture, fuch as that of metals, we do not conceive that the length of the axle has any influence on the fracture. It is otherwife if it be of a fibrous texture like timber: the fibres are bent before breaking, being twifted into fpirals like a cork-fcrew. The length of the axle has fomewhat of the influence of a lever in this cafe, and it is eafier wrenched afunder if long. Accordingly we have found it fo; but we have not been able to reduce this influence to calculation.

129 Concluding remarks.

Our readers are requefted to accept of thefe endeavours to communicate information on this important and difficult fubject. We are duly fenfible of their imperfection, but flatter ourfelves that we have in many inftances pointed out the method which muft be purfued for improving our knowledge on this fubject; and we have given the Englifh reader a more copious lift of experiments on the ftrength of materials than he will meet with in our language. Many ufeful deductions might be made from thefe premifes refpecting the manner of difpofing and combining the ftrength of materials in our ftructures. The beft form of joints, mortifes, tenons, fcarphs; the rules for joggling, tabling, faying, fifhing, &c. practifed in the delicate art of maft-making, are all founded on this doctrine: but the difcuffion of thefe would be equivalent to writing a complete treatife of carpentry. We hope that this will be executed by fome intelligent mechanician, for there is nothing in our language on this fubject but what is almoft contemptible; yet there is no mechanic art that is more fufceptible of fcientific treatment. Such a treatife, if well executed, could not fail of being well received by the public in this age of mechanical improvement.

Strengtheners ‖ Stroking.

STRENGTHENERS, or CORROBORANTS, fuch medicines as are fuppofed to add to the firmnefs of the folids. See MATERIA MEDICA *Index*.

STRETCHING, in *Navigation*, is generally underftood to imply the progreffion of a fhip under a great furface of fail, when clofe-hauled. The difference between this term and *ftanding*, confifts apparently in the quantity of fail; which in the latter may be very moderate; but ftretching generally fignifies excefs; as, we faw the enemy at daybreak ftretching to the fouthward under a croud of fail, &c. *Falconer*.

STRETTO, in Italian mufic, is fometimes ufed to fignify that the meafure is to be fhort and concife, and confequently quick. In this fenfe it ftands oppofed to LARGO.

STRIATED LEAF, among botanifts, one that has a number of longitudinal furrows on its furface.

STRIKE, a meafure of capacity, containing four bufhels. Alfo an inftrument ufed in meafuring corn.

STRIX, the OWL; a genus of birds belonging to the order of accipitres. See ORNITHOLOGY *Index*.

The *bubo*, or great-eared owl inhabits inacceffible rocks and defert places, and preys on hares and feathered game. Its appearance in cities was deemed an unlucky omen; Rome itfelf once underwent a luftration becaufe one of them ftrayed into the capitol. The ancients had them in the utmoft abhorrence; and thought them, like the fcreech-owls, the meffengers of death. Pliny ftyles it *bubo funebris*, and *noctis monftrum*.

Solaque culminibus ferali *carmine* bubo
Sæpe queri et longas in fletum ducere voces. VIRGIL.

Perch'd on the roof, the bird of night complains,
In lengthen'd fhrieks and dire funereal ftrains.

STROBILUS, in *Botany*, a pericarp formed from an amentum by the hardening of the fcales.

STROKING, or rubbing gently with the hand, a method which has been employed by fome perfons for curing difeafes.

Mr Greatrakes or Greatrix, the famous Irifh ftroker, is faid to have performed many wonderful cures. He gives the following account of his difcovery of this art, and of the fuccefs with which he practifed it. "About 1662 I had an impulfe (fays he), or a ftrange perfuafion in my own mind (of which I am not able to give any rational account to another), which did very frequently fuggeft to me, that there was beftowed on me the gift of curing the king's evil; which, for the extraordinarinefs of it, I thought fit to conceal for fome time; but at length I communicated this to my wife, and told her, that I did verily believe that God had given me the bleffing of curing the king's evil; for whether I were in private or public, fleeping or waking, ftill I had the fame impulfe. But her reply to me was, that fhe conceived this was a ftrange imagination; yet, to prove the contrary, a few days after there was one William Mather of Salterbridge in the parifh of Lifmore, who brought his fon William to my houfe, defiring my wife to cure him, who was a perfon ready to afford her charity to her neighbours, according to her fmall fkill in chirurgery.

See *Brief Account of Mr Valentine Greatrakes*, Lond. 1666, 4to.

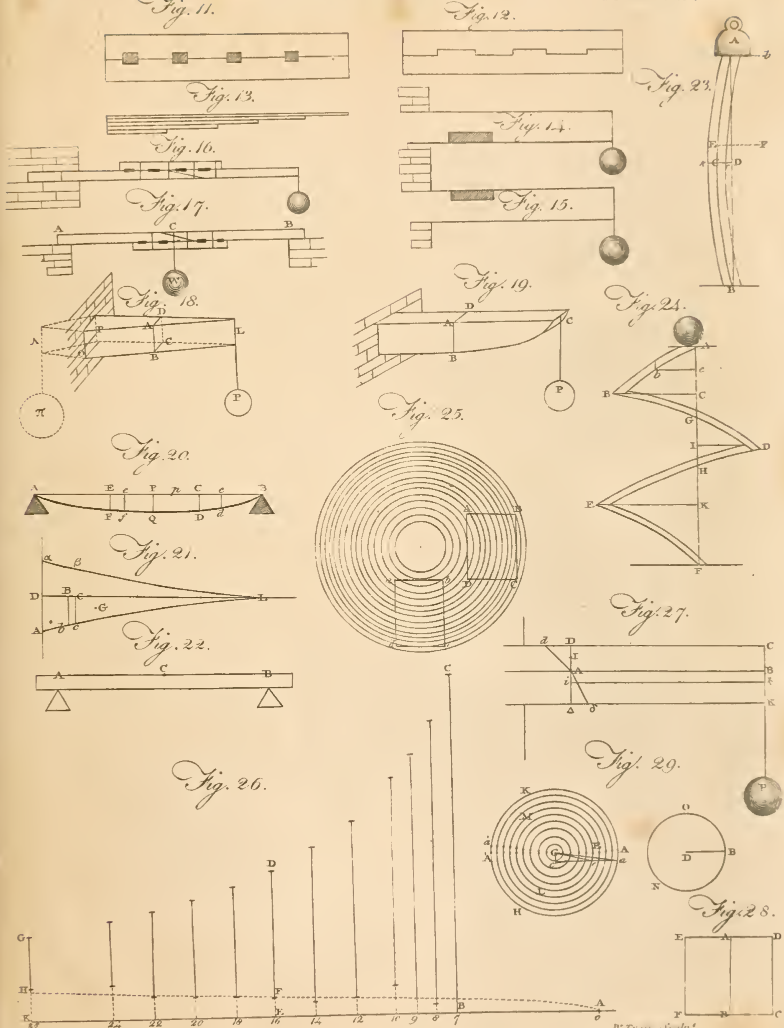
STRENGTH of MATERIALS. Plate DXII.



chirurgery. On which my wife told me, there was one that had the king's evil very grievoufly in the eyes, cheek, and throat; whereupon I told her, that fhe fhould now fee whether this was a bare fancy or imagination, as fhe thought it, or the dictates of God's Spirit on my heart. Then I laid my hands on the places affected, and prayed to God for Jefus fake to heal him; and bid the parent two or three days afterwards to bring the child to me again, which accordingly he did; and I then faw the eye was almoft quite whole; and the node, which was almoft as big as a pullet's egg, was fuppurated; and the throat ftrangely amended; and, to be brief (to God's glory I fpeak it) within a month difcharged itfelf quite, and was perfectly healed, and fo continues, God be praifed."

Then there came to him one Margaret Mackfhane of Ballinecly, in the parifh of Lifmore, who had been afflicted with the evil above feven years, in a much more violent degree; and foon after, his fame increafing, he cured the fame difeafe in many other perfons for three years. He did not meddle all this time with any other diftemper; till about the end of thefe three years, the ague growing epidemical, he found, as formerly, that there was beftowed on him the gift of curing that difeafe. He cured Colonel Phaire, of Cahirmony in the county of Corke, of an ague, and afterwards many other perfons of different diftempers, by ftroking; fo that his name was wonderfully cried up, as if fome divine perfon had been fent from above. January 1665-6, he came over to England, at the requeft of the earl of Orrery; in order to cure the lady of the lord-vifcount Conway, of Ragley in Warwickfhire, who had for many years laboured under a moft violent headache. He ftaid at Ragley three weeks or a month; and though he failed in his endeavours to relieve that lady, he cured vaft numbers of people in thofe parts and at Worcefter.

Though we are no friends to the marvellous, nor believe it poffible that either the king's evil or ague can be cured by ftroking or friction of any kind, whether gentle or fevere, we have no hefitation to acknowledge that many cures might be performed by Mr Greatrakes. Every reflecting perfon who reads the foregoing account which he gives of himfelf will fee that he was an enthufiaft, and believed himfelf guided by a particular revelation; and fuch is the credulity of mankind, that his pretenfions were readily admitted, and men crouded with eagernefs to be relieved of their difeafes. But it is well known to phyficians, that in many cafes the imagination has accomplifhed cures as wonderful as the force of medicine. It is owing chiefly to the influence of imagination that we have fo many accounts from people of veracity of the wonderful effects of quack medicines. We are perfectly affured that thefe medicines, by their natural operation, can never produce the effects afcribed to them; for there is no kind of proportion between the medicine and the effect produced, and often no connection between the medicine and the difeafe.

STROMATEUS, a genus of fifhes belonging to the order of apodes. See ICHTHYOLOGY *Index*.

STROMBOLI, the moft northern of the Lipari iflands. It is a volcano, which conftantly difcharges much fire and fmoke. It rifes in a conical form above the furface of the fea. On the eaft fide it has three or four little craters ranged near each other, not at the fummit, but on the declivity, nearly at two-thirds of its height. But as the furface of the volcano is very rugged and interfected with hollow ways, it may be naturally concluded, that at the time of fome great eruption, the fummit and a part of this fide fell in, as muft have happened alfo to Vefuvius; confequently, the common chimney is at this day on the declivity, although always in the centre of the whole bafe. It is inhabited notwithftanding its fires; but care is taken to avoid the proximity of the crater, which is yet much to be feared. "I was affured (fays M. de Luc) by an Englifhman, who, like me, had the curiofity to vifit thefe ifles, that the fine weather having invited him and his company to land at Stromboli, they afcended a volcano, whofe craters at that time threw out nothing; but that while they were attentively viewing them, unapprehenfive of any danger, they were fuddenly faluted by fuch a furious difcharge, as to be obliged to retreat with precipitation, and not without one of the company being wounded by a piece of fcoria." Of all the volcanoes recorded in hiftory, Stromboli feems to be the only one that burns without ceafing. Etna and Vefuvius often lie quiet for many months, and even years, without the leaft appearance of fire; but Stromboli is ever at work, and for ages paft has been looked upon as the great lighthoufe of thefe feas. E. Long. 15. 45. N. Lat. 30. 0.

STROMBUS, a genus of fhell-fifh. See CONCHOLOGY *Index*.

STRONGOLI, a town of the kingdom of Naples, with a bifhop's fee. It is fituated on a rugged mountain, is about three miles from the fea, and feven north from St Severino. It is fuppofed to be the ancient *Petelia*, which made a confpicuous figure in the fecond Punic war by its obftinate refiftance againft Hannibal. Near its walls Marcellus the rival of Hannibal was flain in a fkirmifh. E. Long. 17. 26. N. Lat. 39. 20.

STRYMON, in *Ancient Geography*, formerly *Conozus*; a river conftituting the ancient limits of Macedonia and Thrace; rifing in Mount Scombrus (Ariftotle). Authors differ as to the modern name of this river.

STRYPE, JOHN, was defcended from a German family, born at London, and educated at Cambridge. He was vicar of Low Layton in Effex, and diftinguifhed himfelf by his compilations of Lives and Memoirs; in which, as Dr Birch remarks, his fidelity and induftry will always give a value to his writings, however deftitute they may be of the graces of ſtyle. He died in 1737, after having enjoyed his vicarage near 68 years.

STUART, Dr Gilbert, was born at Edinburgh in the year 1742. His father Mr George Stuart was profeſſor of humanity in the univerſity, and a man of conſiderable eminence for his claſſical taſte and literature. For theſe accompliſhments he was probably indebted in no ſmall degree to his relation the celebrated Ruddiman, with whom both he and his ſon converſed familiarly, though they afterwards united to injure his fame.

Gilbert having finiſhed his claſſical and philoſophical ſtudies in the grammar-ſchool and univerſity, applied himſelf to juriſprudence, without following, or probably intending to follow, the profeſſion of the law. For that profeſſion he has been repreſented as unqualified by indolence; by a paſſion which at a very early period of life he diſplayed for general literature; or by boundleſs diſſipation:—and all theſe circumſtances may have contributed to make him relinquiſh purſuits in which he could hope to ſucceed only by patient perſeverance and ſtrict decorum of manners. That he did not waſte his youth in idleneſs, is, however, evident from An Hiſtorical Diſſertation concerning the Antiquity of the Britiſh Conſtitution, which he publiſhed before he had completed his twenty-ſecond year, and which had ſo much merit as to induce the univerſity of Edinburgh to confer upon the author, though ſo young a man, the degree of LL.D.

After a ſtudious interval of ſome years, he produced a valuable work, under the title of A View of Society in Europe, in its Progreſs from Rudeneſs to Refinement; or, Inquiries concerning the Hiſtory of Laws, Government, and Manners. He had read and meditated with patience on the moſt important monuments of the middle ages; and in this volume (which ſpeedily reached a ſecond edition) he aimed chiefly at the praiſe of originality and invention; and diſcovered an induſtry that is ſeldom connected with ability and diſcernment. About the time of the publication of the firſt edition of this performance, having turned his thoughts to an academical life, he aſked for the profeſſorſhip of public law in the univerſity of Edinburgh. According to his own account he had been promiſed that place by the miniſter, but had the mortification to ſee the profeſſorſhip beſtowed on another, and all his hopes blaſted by the influence of Dr Robertſon, whom he repreſented as under obligations to him.

To the writer of this article, who was a ſtranger to theſe rival candidates for hiſtorical fame, this part of the ſtory ſeems very incredible; as it is not eaſy to conceive how it ever could be in the power of Dr Stuart to render to the learned Principal any eſſential ſervice. It was believed indeed by the earl of Buchan, and by others, who obſerved that the illiberal jealouſy not unfrequent in the world of letters, was probably the ſource of this oppoſition; which entirely broke the intimacy of two perſons who, before that time, were underſtood to be on the moſt friendly footing with each other. Ingratitude, however, is as likely to have been the vice of Dr Stuart as of Dr Robertſon; for we have been told by a writer *, who, at leaſt in one inſtance, has completely proved what he affirms, that "ſuch was Gilbert Stuart's laxity of principle as a man, that he conſidered ingratitude as one of the moſt venial ſins; ſuch was his conceit as a writer, that he regarded no one's merits but his own; ſuch were his diſappointments, both as a writer and a man, that he allowed his peeviſhneſs to ſour into malice, and indulged his malevolence till it ſettled in corruption."

* *Chalmers in his Life of Ruddiman.*

Soon after this diſappointment, Dr Stuart went to London, where he became from 1768 to 1774 one of the writers of the Monthly Review. In 1772 Dr Adam, rector of the high-ſchool at Edinburgh, publiſhed a Latin Grammar, which he intended as an improvement of the famous Ruddiman's. Stuart attacked him in a pamphlet under the name of *Buſhby*, and treated him with much ſeverity. In doing this, he was probably actuated more by ſome perſonal diſlike of Dr Adam than by regard for the memory of his learned relation; for on other occaſions he ſhowed ſufficiently that he had no regard to Ruddiman's honour as a grammarian, editor, or critic.

In 1774 he returned to his native city, and began the Edinburgh Magazine and Review, in which he diſcuſſed the liberty and conſtitution of England, and diſtinguiſhed himſelf by an inquiry into the character of John Knox the reformer, whoſe principles he reprobated in the ſevereſt terms. About this time he reviſed and publiſhed Sullivan's Lectures on the Conſtitution of England. Soon after he turned his thoughts to the hiſtory of Scotland, and publiſhed Obſervations concerning its Public Law and Conſtitutional Hiſtory; in which he examined with a critical care the preliminary book to Dr Robertſon's Hiſtory. His next work was The Hiſtory of the Reformation; a book which deſerves praiſe for the eaſy dignity of the narrative, and for ſtrict impartiality. His laſt great work, The Hiſtory of Scotland from the Eſtabliſhment of the Reformation to the Death of Queen Mary, which appeared in 1782, has been very generally read and admired. His purpoſe was to vindicate the character of the injured queen, and expoſe the weakneſs of the arguments by which Dr Robertſon had endeavoured to prove her guilty: but though the ſtyle of this work is his own, it contains very little matter which was not furniſhed by Goodall and Tytler; and it is with the arms which theſe two writers put into his hands that Dr Stuart attacked his great antagoniſt.

In 1782 he once more viſited London, and engaged in the Political Herald and Engliſh Review; but the jaundice and dropſy increaſing on him, he returned by ſea to his native country, where he died in the houſe of his father on the 13th of Auguſt 1786.

In his perſon Dr Stuart was about the middle ſize and juſtly proportioned. His countenance was modeſt and expreſſive, ſometimes glowing with ſentiments of friendſhip, of which he was truly ſuſceptible, and at others darting that ſatire and indignation at folly and vice which appear in ſome of his writings. He was a boon companion; and, with a conſtitution that might have ſtood the ſhock of ages, he fell a premature martyr to intemperance. His talents were certainly great, and his writings are uſeful; but he ſeems to have been influenced more by paſſion than prejudice, and in his character there was not much to be imitated.

STUCCO, in building, a compoſition of white marble pulveriſed, and mixed with plaſter of lime; and the whole being ſifted and wrought up with water, is to be uſed like common plaſter: this is called by Pliny *marmoratum opus*, and *albarium opus*.

A patent has been granted to Mr B. Higgins for inventing a new kind of ſtucco, or water-cement, more firm and durable than any heretofore. Its compoſition, as extracted from the ſpecification ſigned by himſelf, is as follows: "Drift-ſand, or quarry (A) ſand, which conſiſts chiefly of hard quartoſe flat-faced grains with ſharp angles; which is the freeſt, or may be moſt eaſily freed by waſhing, from clay, ſalts, and calcareous, gypſeous, or other grains leſs hard and durable than quartz; which contains the ſmalleſt quantity of pyrites or heavy metallic matter inſeparable by waſhing; and which ſuffers the ſmalleſt diminution of its bulk in waſhing in the following manner—is to be preferred before any other. And where a coarſe and a fine ſand of this kind, and correſponding in the ſize of their grains with the coarſe and fine ſands hereafter deſcribed, cannot be eaſily procured, let ſuch ſand of the foregoing quality be choſen as may be ſorted and cleanſed in the following manner:

"Let the ſand be ſifted in ſtreaming clear water, through a ſieve which ſhall give paſſage to all ſuch grains as do not exceed one-ſixteenth of an inch in diameter; and let the ſtream of water and the ſifting be regulated ſo that all the ſand, which is much finer than the Lynn-ſand commonly uſed in the London glaſs-houſes, together with clay and every other matter ſpecifically lighter than ſand, may be waſhed away with the ſtream, whilſt the purer and coarſer ſand, which paſſes through the ſieve, ſubſides in a convenient receptacle, and whilſt the coarſe rubbiſh and rubble remain on the ſieve to be rejected.

"Let the ſand which thus ſubſides in the receptacle be waſhed in clean ſtreaming water through a finer ſieve, ſo as to be further cleanſed and ſorted into two parcels; a coarſer, which will remain in the ſieve which is to give paſſage to ſuch grains of ſand only as are leſs than one-thirtieth of an inch in diameter, and which is to be ſaved apart under the name of *coarſe ſand*: and a finer, which will paſs through the ſieve and ſubſide in the water, and which is to be ſaved apart under the name of *fine ſand*.—Let the coarſe and the fine ſand be dried ſeparately, either in the ſun or on a clean iron-plate, ſet on a convenient ſurface, in the manner of a ſand-heat (B).

"Let lime be choſen (C) which is ſtone-lime, which heats the moſt in ſlaking, and ſlakes the quickeſt when duly watered; which is the freſheſt made and cloſeſt kept; which diſſolves in diſtilled vinegar with the leaſt effervescence, and leaves the ſmalleſt reſidue inſoluble, and in this reſidue the ſmalleſt quantity of clay, gypſum, or martial matter.

"Let the lime choſen according to theſe important rules be put in a braſs-wired ſieve to the quantity of 14 pounds. Let the ſieve be finer than either of the foregoing; the finer, the better it will be: let the lime be ſlaked (D) by plunging it in a butt filled with ſoft water, and raiſing it out quickly and ſuffering it to heat and fume, and by repeating this plunging and raiſing alternately, and agitating the lime, until it be made to paſs through the ſieve into the water; and let the part of the lime which does not eaſily paſs through the ſieve be rejected: and let freſh portions of the lime be thus uſed, until as many (E) ounces of lime have paſſed through the ſieve as there are quarts of water in the butt. Let the water thus impregnated ſtand in the butt cloſely covered (F) until it becomes clear; and through wooden (G) cocks placed at different heights in the butt), let the clear liquor be drawn off as faſt (H) and as

(A) "This is commonly called *pit-ſand*.

(B) "The ſand ought to be ſtirred up continually until it is dried, and is then to be taken off; for otherwiſe the evaporation will be very ſlow, and the ſand which lies next the iron plate, by being overheated, will be diſcoloured.

(C) "The preference given to ſtone-lime is founded on the preſent practice in the burning of lime, and on the cloſer texture of it, which prevents it from being ſo ſoon injured by expoſure to the air as the more ſpongy chalk-lime is; not on the popular notion that ſtone-lime has ſomething in it whereby it excels the beſt chalk in the cementing properties. The gypſum contained in lime-ſtone remains unaltered, or very little altered, in the lime, after the burning; but it is not to be expected that clay or martial matter ſhould be found in their native ſtate in well-burned lime; for they concrete or vitrify with a part of the calcareous earth, and conſtitute the hard grains or lumps which remain undiſſolved in weak acids, or are ſeparable from the ſlaked lime by ſifting it immediately through a ſieve.

(D) "This method of impregnating the water with lime is not the only one which may be adopted. It is, however, preferred before others, becauſe the water clears the ſooner in conſequence of its being warmed by the ſlaking lime; and the gypſeous part of the lime does not diffuſe itſelf in the water ſo freely in this way as it does when the lime is ſlaked to fine powder in the common method, and is then blended with the water; for the gypſeous part of the lime ſlakes at firſt into grains rather than into fine powder, and will remain on the ſieve after the pure lime has paſſed through, long enough to admit of the intended ſeparation; but when the lime is otherwiſe ſlaked, the gypſeous grains have time to ſlake to a finer powder, and paſſing through the ſieve, diſſolve in the water along with the lime. I have imagined that other advantages attended this method of preparing the lime-water, but I cannot yet ſpeak of them with preciſion.

(E) "If the water contains no more acidulous gas than is uſually found in river or rain water, a fourth part of this quantity of lime, or leſs, will be ſufficient.

(F) "The calcareous cruſt which forms on the ſurface of the water ought not to be broken, for it aſſiſts in excluding the air, and preventing the abſorption of acidulous gas whereby the lime-water is ſpoiled.

(G) "Braſs-cocks are apt to colour a part of the liquor.

(H) "Lime-water cannot be kept many days unimpaired, in any veſſels that are not perfectly air-tight. If the liquor be drawn off before it clears, it will contain whiting, which is injurious; and if it be not inſtantly uſed as low as the lime fubfides, for ufe. This clear liquor I call the *cementing liquor* (I). The freer the water is from faline matter, the better will be the cementing liquor made with it.

"Let 56 pounds of the aforefaid chofen lime be flaked, by gradually fprinkling on it, and efpecially on the unflaked pieces, the cementing liquor, in a clofe (K) clean place. Let the flaked part be immediately (L) fifted through the laft-mentioned fine brafs-wired fieve: Let the lime which paffes be ufed inftantly, or kept in air-tight veffels, and let the part of the lime which does not pafs through the fieve be rejected (M).—This finer richer part of the lime which paffes through the fieve I call *purified lime*.

"Let bone-afh be prepared in the ufual manner, by grinding the whiteft burnt bones, but let it be fifted, to be much finer than the bone-afh commonly fold for making cupels.

"The moft eligible materials for making my cement being thus prepared, take 56 pounds of the coarfe fand and 42 pounds of the fine fand; mix them on a large plank of hard wood placed horizontally; then fpread the fand fo that it may ftand to the height of fix inches, with a flat furface on the plank; wet it with the cementing liquor; and let any fuperfluous quantity of the liquor, which the fand in the condition defcribed cannot retain, flow away off the plank. To the wetteft fand add 14 pounds of the putrefied lime in feveral fucceffive portions, mixing and beating them up together in the mean time with the inftruments generally ufed in making fine mortar: then add 14 pounds of the bone-afh in fucceffive portions, mixing and beating all together. The quicker and the more perfectly thefe materials are mixed and beaten together, and the fooner the cement thus formed is ufed, the better (N) it will be. This I call the *water-cement coarfe-grained*, which is to be applied in building, pointing, plaftering, ftuccoing, or other work, as mortar and ftucco now are; with this difference chiefly, that as this cement is fhorter than mortar or common ftucco, and dries fooner, it ought to be worked expeditioufly in all cafes; and in ftuccoing, it ought to be laid on by fliding the trowel upwards on it; that the materials ufed along with this cement in building, or the ground on which it is to be laid in ftuccoing, ought to be well wetted with the cementing liquor in the inftant of laying on the cement; and that the cementing liquor is to be ufed when it is neceffary to moiften the cement, or when a liquid is required to facilitate the floating of the cement.

"When fuch cement is required to be of a finer texture, take 98 pounds of the fine fand, wet it with the cementing liquor, and mix it with the purified lime and the bone-afh in the quantities and in the manner above defcribed; with this difference only, that 15 pounds of lime, or (O) thereabouts, are to be ufed inftead of 14 pounds, if the greater part of the fand be as fine as Lynn-fand. This I call *water-cement fine-grained*. It is to be ufed in giving the laft coating, or the finifh to any work intended to imitate the finer-grained ftones or ftucco. But it may be applied to all the ufes of the water-cement coarfe-grained, and in the fame manner.

"When for any of the foregoing purpofes of pointing, building, &c. fuch a cement is required much cheaper and coarfer-grained, then much coarfer clean fand than the foregoing coarfe fand, or well-wafhed fine rubble, is to be provided. Of this coarfe fand or rubble take 56 pounds, of the foregoing coarfe fand 28 pounds, and of the fine fand 14 pounds; and after mixing thefe, and wetting them with the cementing liquor in the foregoing manner, add 14 pounds, or fomewhat lefs, of the (P) purified lime, and then 14 pounds or fomewhat lefs

ufed after it is drawn limpid from the butt into open veffels, it will grow turbid again, and depofit the lime changed to whiting by the gas abforbed from the air. The calcareous matter which fubfides in the butt refembles whiting the more nearly as the lime has been more fparingly employed; in the contrary circumftances, it approaches to the nature of lime; and in the intermediate ftate, it is fit for the common compofition of the plafterers for infide ftucco.

(I) "At the time of writing this fpecification, I preferred this term before that of lime-water, on grounds which I had not fufficiently examined.

(K) "The vapour which arifes in the flaking of lime contributes greatly to the flaking of thefe pieces which lie in its way; and an unneceffary wafte of the liquor is prevented, by applying it to the lime heaped in a pit or in a veffel, which may reftrain the iffue of the vapour, and direct it through the mafs. If more of the liquor be ufed than is neceffary to flake the lime, it will create error in weighing the flaked powder, and will prevent a part of it from paffing freely through the fieve. The liquid is therefore to be ufed fparingly, and the lime which has efcaped its action is to be fprinkled apart with frefh liquor.

(L) "When the aggregation of the lumps of lime is thus broken, it is impaired much fooner than it is in the former ftate, becaufe the air more freely pervades it.

(M) "Becaufe it confifts of heterogeneous matter or of ill-burnt lime; which laft will flake and pafs through the fieve, if the lime be not immediately fifted after the flaking, agreeable to the text.

(N) "Thefe proportions are intended for a cement made with fharp fand, for incruftation in expofed fituations, where it is neceffary to guard againft the effects of hot weather and rain. In general, half this quantity of bone-afhes will be found fufficient; and although the incruftation in this latter cafe will not harden deeply fo foon, it will be ultimately ftronger, provided the weather be favourable.

"The injuries which lime and mortar fuftain by expofure to the air, before the cement is finally placed in a quiefcent ftate, are great; and therefore our cement is the worfe for being long beaten, but the better as it is quickly beaten until the mixture is effected, and no longer.

(O) "The quantity of bone-afhes is not to be increafed with that of the lime; but it is to be leffened as the expofure and purpofes of the work will admit.

(P) "Becaufe lefs lime is neceffary, as the fand is coarfer.

lefs of the bone-afh, mixing them together in the manner already defcribed. When my cement is required to be white, white fand, white lime, and the whiteft bone-afh are to be chofen. Gray fand, and gray bone-afh formed of half-burnt bones, are to be chofen to make the cement gray; and any other colour of the cement is obtained, either by choofing coloured fand, or by the admixture of the neceffary quantity of coloured talc in powder, or of coloured, vitreous, or metallic powders, or other durable colouring ingredients commonly ufed in paint.

"To the end that fuch a water-cement as I have defcribed may be made as ufeful as it is poffible in all circumftances; and that no perfon may imagine that my claim and right under thefe letters-patent may be eluded by divers variations, which may be made in the foregoing procefs without producing any notable defect in the cement; and to the end that the principles of this art, as well as the art itfelf, of making my cement, may be gathered from this fpecification and perpetuated to the public; I fhall add the following obfervations:

"This my water-cement, whether the coarfe or fine grained, is applicable in forming artificial ftone, by making alternate layers of the cement and of flint, hard ftone, or brick, in moulds of the figure of the intended ftone, and by expofing the maffes fo formed to the open (Q) air to harden.

"When fuch cement is required for water (R) fences, two-thirds of the prefcribed quantity of bone-afhes are to be omitted; and in the place thereof an equal meafure of powdered terras is to be ufed; and if the fand employed be not of the coarfeft fort, more terras muft be added, fo that the terras fhall be by weight one-fixth part of the weight of the fand.

"When fuch a cement is required of the fineft grain (S) or in a fluid form, fo that it may be applied with a brufh, flint powder, or the powder of any quartofe or hard earthy fubftance, may be ufed in the place of fand; but in a quantity fmaller, as the flint or other powder is finer; fo that the flint-powder, or other fuch powder, fhall not be more than fix times the weight of the lime, nor lefs than four times its weight. The greater the quantity of lime within thefe limits, the more will the cement be liable to crack by quick drying, and *vice verfa*.

"Where fuch fand as I prefer cannot be conveniently procured, or where the fand cannot be conveniently wafhed and forted, that fand which moft refembles the mixture of coarfe and fine fand above prefcribed, may be ufed as I have directed, provided due attention is paid to the quantity of the lime, which is to be greater (T) as the quantity is finer, and *vice verfa*.

"Where fand cannot be eafily procured, any durable ftony body, or baked earth grofsly powdered (U), and forted nearly to the fizes above prefcribed for fand, may be ufed in the place of fand, meafure for meafure, but not weight for weight, unlefs fuch grofs powder be as heavy fpecifically as fand.

"Sand may be cleanfed from every fofter, lighter, and lefs durable matter, and from that part of the fand which is too fine, by various methods preferable (X), in certain circumftances, to that which I have defcribed.

"Water may be found naturally free from fixable gas, felenite, or clay; fuch water may, without any notable inconvenience, be ufed in the place of the cementing liquor; and water approaching this ftate will not require fo much lime as I have ordered to make the cementing liquor; and a cementing liquor fufficiently ufeful may be made by various methods of mixing lime and water in the defcribed proportions, or nearly fo.

"When ftone-lime cannot be procured, chalk-lime, or fhell-lime, which beft refembles ftone-lime, in the characters above written of lime, may be ufed in the manner

(Q) "But they muft not be expofed to the rain until they are almoft as ftrong as frefh Portland ftone; and even then they ought to be fheltered from it as much as the circumftances will admit. Thefe ftones may be made very hard and beautiful, with a fmall expence of bone-afh, by foaking them, after they have dried thoroughly and hardened, in the lime liquor, and repeating this procefs twice or thrice, at diftant intervals of time. The like effect was experienced in incruftations.

(R) "In my experiments, mortar made with terras-powder, in the ufual method, does not appear to form fo ftrong a cement for water-fences as that made, according to the fpecification, with coarfe fand; and I fee no more reafon for avoiding the ufe of fand in terras-mortar, than there would be for rejecting ftone from the embankment. The bone-afhes meant in this place are the dark gray or black fort. I am not yet fully fatisfied about the operation of them in this inftance.

(S) "The qualities and ufes of fuch fine calcareous cement are recommended chiefly for the purpofe of fmoothing and finifhing the ftronger cruftaceous works, or for wafhing walls to a lively and uniform colour. For this laft intention, the mixture muft be as thin as new cream, and laid on brifkly with a brufh, in dry weather; and a thick and durable coat is to be made by repeated wafhing; but is not to be attempted by ufing a thicker liquor; for the coat made with this laft is apt to fcale, whilft the former endures the weather much longer than any other thin calcareous covering that has been applied in this way. Fine yellow-ochre is the cheapeft colouring ingredient for fuch wafh, when it is required to imitate Bath-ftone, or the warm-white ftones.

(T) "If fea-fand be well wafhed in frefh water, it is as good as any other round fand.

(U) "The cement made with thefe and the proper quantities of purified lime and lime-water, are inferior to the beft, as the grains of thefe powders are more perifhable and brittle than thofe of fand. They will not therefore be employed, unlefs for the fake of evafion, or for want of fand: in this latter cafe, the finer powder ought to be wafhed away.

(X) "This and the next paragraph is inferted with a view to evafions, as well as to fuggeft the eafier and cheaper methods which may be adopted in certain circumftances, by artifts who underftand the principles which I endeavoured to teach.

manner deſcribed, except that fourteen pounds and a half of chalk-lime will be required in the place of fourteen pounds of ſtone-lime. The proportion of lime which I have preſcribed above may be increaſed without inconvenience, when the cement or ſtucco is to be applied where it is not liable to dry quickly; and in the contrary circumſtance, this proportion may be diminiſhed; and the defect of lime in quantity or quality may be very advantageouſly ſupplied (Y), by cauſing a conſiderable quantity of the cementing liquor to ſoak into the work, in ſucceſſive portions, and at diſtant intervals of time, ſo that the calcareous matter of the cementing liquor, and the matter attracted from the open air, may fill and ſtrengthen the work.

"The powder of almoſt every well-dried or burnt animal ſubſtance may be uſed inſtead of bone-aſh; and ſeveral earthy powders, eſpecially the micaceous and the metallic; and the elixated aſhes of divers vegetables whoſe earth will not burn to lime; and the aſhes of mineral fuel, which are of the calcareous kind, but will not burn to lime, will anſwer the ends of bone-aſh in ſome degree.

"The quantity of bone-aſh deſcribed may be leſſened without injuring the cement, in thoſe circumſtances eſpecially which admit the quantity of lime to be leſſened, and in thoſe wherein the cement is not liable to dry quickly. And the art of remedying the defects of lime may be advantageouſly practiſed to ſupply the deficiency of bone aſh, eſpecially in building, and in making artificial ſtone with this cement."

STUD, in the manege, a collection of breeding horſes and mares.

STUDDING-SAILS, certain light ſails extended, in moderate and ſteady breezes, beyond the ſkirts of the principal ſails, where they appear as wings upon the yard arms.

STUFF, *in Commerce*, a general name for all kinds of fabrics of gold, ſilver, ſilk, wool, hair, cotton, or thread, manufactured on the loom; of which number are velvets, brocades, mohairs, ſatins, taffetas, cloths, ſerges, &c.

STUKELY, DR WILLIAM, a celebrated antiquarian, deſcended from an ancient family in Lincolnſhire, was born at Holbech in 1687, and educated in Bennet college, Cambridge. While an under graduate, he often indulged a ſtrong propenſity to drawing and deſigning; but made phyſic his principal ſtudy, and firſt began to practiſe at Boſton in his native country. In 1717 he removed to London, where, on the recommendation of Dr Mead, he was ſoon after elected a fellow of the Royal Society; he was one of the firſt who revived that of the antiquarians in 1718, and was their ſecretary for many years during his reſidence in town. In 1729 he took holy orders by the encouragement of Archbiſhop Wake; and was ſoon after preſented by Lord-chancellor King with the living of All-Saints in Stamford. In 1741 he became one of the founders of the Egyptian ſociety, which brought him acquainted with the benevolent duke of Montague, one of the members; who prevailed on him to leave Stamford, and preſented him to the living of St George the Martyr, Queen Square. He died of a ſtroke of the palſy in 1765. In his phyſical capacity, his Diſſertation on the Spleen was well received; and his *Itinerarium Curioſum*, the firſt fruit of his juvenile excurſions, was a good ſpecimen of what was to be expected from his riper age. His great learning, and profound reſearches into the dark remains of antiquity, enabled him to publiſh many elaborate and curious works: his friends uſed to call him the *arch-druid* of his age. His diſcourſes, intitled *Palæographia Sacra*, on the vegetable creation, beſpeak him a botaniſt, philoſopher, and divine.

STUM, in the wine-trade, denotes the unfermented juice of the grape after it has been ſeveral times racked off and ſeparated from its ſediment. The caſks are for this purpoſe well matched or fumigated with brimſtone every time, to prevent the liquor from fermenting, as it would otherwiſe readily do, and become wine. See MUST.

STUPIDITY. The Greek word μωροτης correſponds moſt with our Engliſh word *ſtupidity* or *fooliſhneſs*, when uſed to expreſs that ſtate of mind in which the intellects are defective. The immediate cauſes are ſaid to be, a deficiency of vital heat, or a defect in the brain. Stupid children ſometimes become ſprightly youths; but if ſtupidity continues to the age of puberty, it is hardly ever removed. If ſtupidity follows upon a violent paſſion, an injury done to the head, or other evident cauſe, and if it continues long, it becomes incurable. But the ſtupidity which conſiſts in a loſs of memory, and ſucceeds a lethargy, ſpontaneouſly ceaſes when the lethargy is cured.

STUPOR, a numbneſs in any part of the body, whether occaſioned by ligatures obſtructing the blood's motion, by the palſy, or the like.

STUPPA, or STUPE, in *Medicine*, is a piece of cloth dipped in ſome proper liquor, and applied to an affected part.

STURDY, a diſtemper to which cattle are ſubject, called alſo the *turning evil*. See FARRIERY *Index*.

STURGEON. See ACCIPENSER, ICHTHYOLOGY *Index*.

STURMIUS, JOHN, a learned philologer and rhetorician, was born at Sleida in Eifel near Cologne in 1507. He ſtudied at firſt in his native country with the ſons of Count de Manderſcheid, whoſe receiver his father was. He afterwards purſued his ſtudy at Liege in the college of St Jerom, and then went to Louvain in 1524. Five years he ſpent there, three in learning and two in teaching. He ſet up a printing-preſs with Rudger Reſcius profeſſor of the Greek tongue, and printed ſeveral Greek authors. He went to Paris in 1529, where he was highly eſteemed, and read public lectures on the Greek and Latin writers, and on logic. He married there, and kept a great number of boarders: but as he liked what were called the *new opinions*, he was more than once in danger; and this undoubtedly was the reaſon why he removed to Straſburg in 1537, in order to take poſſeſſion of the place offered him by the magiſtrates. The year following he opened a ſchool, which became

(Y) "This practice is noticed, as the remedy which may be uſed for the defects ariſing from evaſive meaſures, and as the method of giving ſpongy incruſtations containing bone-aſhes the greateſt degree of hardneſs."

became famous, and by his means obtained of Maximilian II. the title of an univerſity in 1566. He was very well ſkilled in polite literature, wrote Latin with great purity, and was a good teacher. His talents were not confined to the ſchool; for he was frequently intruſted with deputations in Germany and foreign countries, and diſcharged theſe employments with great honour and diligence. He ſhowed extreme charity to the refugees on account of religion: He not only laboured to aſſiſt them by his advice and recommendations; but he even impoveriſhed himſelf for them. He died in his 82d year, after he had been for ſome time blind. He publiſhed many books; the principal of which are, 1. *Partitiones Dialecticæ*. 2. *De Educatione Principum*. 3. *De Nobilitate Anglicana*. 4. *Linguæ Latinæ reſolvendæ Ratio*. 5. Excellent Notes on Ariſtotle's and Hermogenes's Rhetoric, &c.

He ought not to be confounded with *John Sturmius*, a native of Mechlin, and phyſician and profeſſor of mathematics at Louvain, who alſo wrote ſeveral works.

STURNUS, the STARLING; a genus of birds belonging to the order of paſſeres. See ORNITHOLOGY *Index*.

STYE, or STYTHE, in the eye. See CRITHE.

STYLE, a word of various ſignifications, originally deduced from *ſtylos*, a kind of bodkin wherewith the ancients wrote on plates of lead, or on wax, &c. and which is ſtill uſed to write on ivory-leaves and paper prepared for that purpoſe, &c.

STYLE, in dialling, denotes the gnomon or cock of a dial raiſed on the plane thereof to project a ſhadow.

STYLE, in *Botany*. See BOTANY.

STYLE, in language, is the peculiar manner in which a man expreſſes his conceptions. It is a picture of the ideas which riſe in his mind, and of the order in which they are there produced.

The qualities of a good ſtyle may be ranked under two heads; perſpicuity and ornament. It will readily be admitted, that perſpicuity ought to be eſſentially connected with every kind of writing; and to attain it, attention muſt be paid, firſt to ſingle words and phraſes, and then to the conſtruction of ſentences. When conſidered with reſpect to words and phraſes, it requires theſe three qualities; purity, propriety, and preciſion. When conſidered with regard to ſentences, it requires a clear arrangement of the words and unity in the ſenſe; to which, if ſtrength and harmony be added, the ſtyle will become ornamented.

One of the moſt important directions to be obſerved by him who wiſhes to form a good ſtyle, is to acquire clear and preciſe ideas on the ſubject concerning which he is to write or ſpeak. To this muſt be added frequency of compoſition, and an acquaintance with the ſtyle of the beſt authors. A ſervile imitation, however, of any author is carefully to be avoided; for he who copies, can hardly avoid copying faults as well as beauties. A ſtyle cannot be proper unleſs it be adapted to the ſubject, and likewiſe to the capacity of our hearers, if we are to ſpeak in public. A ſimple, clear, and unadorned ſtyle, ſuch as that of Swift, is fitteſt for intricate diſquiſition; a ſtyle elegant as Addiſon's, or impetuous like Johnſon's, is moſt proper for fixing the attention on truths, which, though known, are too much neglected. We muſt not be inattentive to the ornaments of ſtyle, if we wiſh that our labours ſhould be read and admired; but he is a contemptible writer, who looks not beyond the dreſs of language, who lays not the chief ſtreſs upon his matter, and who does not regard ornament as a ſecondary and inferior recommendation. For further obſervations on the different kinds of ſtyle, ſee ORATORY, N° 99, &c.

STYLE, in *Juriſprudence*, the particular form or manner of proceeding in each court of juriſdiction, agreeable to the rules and orders eſtabliſhed therein: thus we ſay, the ſtyle of the court of Rome, of chancery, of parliament, of the privy-council, &c.

STYLE, in *Muſic*, denotes a peculiar manner of ſinging, playing, or compoſing; being properly the manner that each perſon has of playing, ſinging, or teaching; which is very different both in reſpect of different geniuſes, of countries, nations, and of the different matters, places, times, ſubjects, paſſions, expreſſions, &c. Thus we ſay, the ſtyle of Paleſtrina, of Lully, of Corelli, of Handel, &c.; the ſtyle of the Italians, French, Spaniards, &c.

Old STYLE, the Julian method of computing time, as the

New STYLE is the Gregorian method of computation. See KALENDAR.

STYLEPHORUS CHORDATUS, a genus of fiſhes belonging to the order of apodes. See ICHTHYOLOGY *Index*, and Tranſactions of the Linnæan Society, vol. i.

STYLET, a ſmall dangerous kind of poniard which may be concealed in the hand, chiefly uſed in treacherous aſſaſſinations. The blade is uſually triangular, and ſo ſmall that the wound it makes is almoſt imperceptible.

STYLITES, PILLAR SAINTS, in eccleſiaſtical hiſtory, an appellation given to a kind of ſolitaries, who ſtood motionleſs upon the tops of pillars, raiſed for this exerciſe of their patience, and remained there for ſeveral years, amidſt the admiration and applauſe of the ſtupid populace. Of theſe we find ſeveral mentioned in ancient writers, and even as low as the twelfth century, when they were totally ſuppreſſed.

The founder of the order was St Simeon Stylites, a famous anchoret in the fifth century, who firſt took up his abode on a column ſix cubits high; then on a ſecond of twelve cubits, a third of twenty-two, a fourth of thirty-ſix, and on another of forty cubits, where he thus paſſed thirty-ſeven years of his life. The tops of theſe columns were only three feet in diameter, and were defended by a rail that reached almoſt to the girdle, ſomewhat reſembling a pulpit. There was no lying down in it. The faquirs, or devout people of the Eaſt, imitate this extraordinary kind of life to this day.

STYLOCERALOIDES, STYLO-GLOSSUS, *STYLO-Hyoidæus*, *STYLO-Pharyngæus*, STYLOIDES,	The names of different muſcles in the human body. See *Table of the Muſcles* under ANATOMY.

STYLOSANTHES, a genus of plants belonging to the *diadelphia* claſs, and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

STYPTIC, in *Pharmacy*, a medicine which by its aſtringency ſtops hæmorrhagies, &c. See MATERIA MEDICA *Index*.

STYRAX, the STORAX-TREE, a genus of plants belonging to the claſs *decandria*, and in the natural ſyſtem ranging

ranging under the 18th order, *bicornes*. See BOTANY and MATERIA MEDICA *Index*.

STYX, in *Fabulous Hiſtory*, a celebrated river of hell, round which it flows nine times. The gods held the waters of the Styx in ſuch veneration, that to ſwear by them was reckoned an oath altogether inviolable. If any of the gods had perjured themſelves, Jupiter obliged them to drink the waters of the Styx, which lulled them for one whole year into a ſenſeleſs ſtupidity, for the nine following years they were deprived of the ambroſia and the nectar of the gods, and after the expiration of the years of their puniſhment, they were reſtored to the aſſembly of the deities, and to all their original privileges. It is ſaid that this veneration was ſhown to the Styx, becauſe it received its name from the nymph Styx, who with her three daughters aſſiſted Jupiter in his war againſt the Titans.

Styx was a river which it was neceſſary for departed ſhades to paſs before they could enter the infernal regions; and it was the office of Charon to ferry them over in a boat which was kept for that purpoſe. The ghoſts of thoſe who had not been honoured with the rites of ſepulture were obliged to wander an hundred years before Charon could admit them into his boat to convey them before the judges of Hades. What could have given riſe to this fable of Charon and his boat, it is not very material to inquire. Mythological writers have ſaid, that the Greeks learned it from the Egyptians, which is indeed probable enough; that the Egyptians framed both this, and ſome other fables relating to the dead, from certain cuſtoms peculiar to their country; that in particular there was, not far from Memphis, a famous burying-place, to which the dead bodies were conveyed in a boat acroſs the lake Acheruſia; and that Charon was a boatman who had long officiated in that ſervice. The learned Dr Blackwell ſays, in his life of Homer, that, in the old Egyptian language, *Charoni* ſignified "ferryman."

Tranſactions of the Royal Society of Edinburgh, vol. ii.

SUABIA, a circle of Germany, bounded on the north by the circle of Franconia and that of the Lower Rhine; on the weſt by the circle of the Lower Rhine and Alſace; on the ſouth by Switzerland; and on the eaſt by the circle of Bavaria. Of all the circles of the empire, Suabia is the moſt divided; it contains four eccleſiaſtic and thirteen lay principalities, nineteen independent prelacies and abbeys, twenty-ſix earldoms and lordſhips, and thirty-one free cities. The prime directors of the circle, as they are termed, were formerly the biſhop of Conſtance and the duke of Wirtemberg. But this circle has ſuffered ſimilar changes with neighbouring ſtates.

The mixture of the various forms of government and religious ſects; the oppreſſion exerciſed by the great on the poor; the game conſtantly played by the emperor, who poſſeſſes many pieces of detached country in Suabia, which depend not on the circle, and can, in conſequence of his privileges as archduke of Auſtria, extend his poſſeſſions in it by various ways; are circumſtances (ſays Baron Rieſbeck) which give the cultivation of the country, and the character of the inhabitants, a moſt extraordinary caſt. In ſeveral of the poſt towns where you ſtop, you ſee the higheſt degree of cultivation in the midſt of the moſt ſavage wildneſs; a great degree of knowledge and poliſh of manners, mixed with the groſſeſt ignorance and ſuperſtition; traces of liberty, under the deepeſt oppreſſion; national pride, together with the contempt and neglect of the native country; in ſhort, all the ſocial qualities in ſtriking contraſt and oppoſition to each other. Thoſe parts of Suabia which belong to the great potentates, ſuch as Wirtemberg, Auſtria, and Baden, are certainly the moſt improved. The whole of Suabia may comprehend about nine hundred German ſquare miles, and two millions of people. More than half of theſe are ſubjects of the three above mentioned princes, though they are not proprietors of near one half of the lands.

Baron Rieſbeck's Travels through Germany, vol. i.

SUARES, FRANCIS, a Jeſuit, was born in Granada on the 5th of January 1548. He was a profeſſor of theology at Alcala, Salamanca, Rome, and Coimbra in Portugal. He died at Liſbon in 1617 with the greateſt reſignation; "I never thought (ſaid he) that it was ſo eaſy to die." His memory was aſtoniſhing, he could repeat the whole of his voluminous works by heart. His writings fill 23 folio volumes, and are moſtly on theological and moral ſubjects. His Treatiſe of Laws has been reprinted in this country. His Defence of the Catholic Faith againſt the Errors of England was written at the requeſt of Pope Paul V. This book was publicly burnt at London by order of James I. When Suares heard it, he is ſaid to have exclaimed, "O that I too could ſeal with my blood the truths which I have defended with my pen!"

SUBAH, the general name of the viceroyſhips, or greater governments, into which the Mogul empire was divided, conſiſting of ſeveral provinces. The juriſdiction of a ſubahdar, the ſame as ſubahſhip, ſubaedaree, or nizamut.

SUBAHDAR, the viceroy, lord-lieutenant, or governor, holding a ſubah; the ſame as nabob or nazim. Alſo the black commander of a company of ſeapoys.

SUBALTERN, a ſubordinate officer, or one who diſcharges his poſt under the command and ſubject to the direction of another; ſuch are lieutenants, ſublieutenants, cornets, and enſigns, who ſerve under the captain.

SUBCLAVIAN, in *Anatomy*, is applied to any thing under the armpit or ſhoulder, whether artery, nerve, vein, or muſcle.

SUBDEACON, an inferior miniſter, who anciently attended at the altar, prepared the ſacred veſſels, delivered them to the deacons in time of divine ſervice, attended the doors of the church during communion-ſervice, went on the biſhop's embaſſies with his letters or meſſages to foreign churches, and was inveſted with the firſt of the holy orders. They were ſo ſubordinate to the ſuperior rulers of the church, that, by a canon of the council of Laodicea, they were forbidden to ſit in the preſence of a deacon without his leave. According to the canons, a perſon muſt be twenty-two years of age to be promoted to the order of ſubdeacon. See DEACON.

SUBDOMINANT, in *Muſic*, a name given by M. Rameau to the fourth note of the tone, which of conſequence is the ſame interval from the tonic when deſcending as the dominant in riſing. This denomination ariſes from the affinity which this author finds by inverſion between the minor mode of the ſubdominant and the major mode of the tonic.

SUBDUPLE RATIO, is when any number or quantity is contained in another twice. Thus 3 is ſaid to be ſubduple of 6, as 6 is duple of 3. See RATIO.

SUBDUPLICATE RATIO of any two quantities, is the ratio of their square roots.

SUBER, the CORK-TREE. See QUERCUS, BOTANY *Index*.

SUBJECT, a person under the rule and dominion of a sovereign prince or state.

SUBJECT is also used for the matter of an art or science, or that which it considers, or whereon it is employed: thus the human body is the subject of medicine.

SUBINFEUDATION, was where the inferior lords, in imitation of their superiors, began to carve out and grant to others minuter estates than their own, to be held of themselves; and were so proceeding downwards *in infinitum*, till the superior lords observed, that by this method of subinfeudation they lost all their feodal profits, of wardships, marriages, and escheats, which fell into the hands of these mesne or middle lords, who were the immediate superiors of the terre-tenant, or him who occupied the land. This occasioned the stat. of Westm. 3. or *quia emptores*, 18. Edw. I. to be made; which directs, that, upon all sales or feoffments of lands, the feoffee shall hold the same, not of his immediate feoffer, but of the chief lord of the fee of whom such feoffer himself held it. And from hence it is held, that all manors existing at this day must have existed by immemorial prescription; or at least ever since the 18 Edw. I. when the statute of *quia emptores* was made.

Blackst. Commentary, vol. ii.

SUBITO, in the Italian music, is used to signify that a thing is to be performed quickly and hastily: thus we meet with *volti subito*, turn over the leaf quickly.

SUBJUNCTIVE, in *Grammar*. See GRAMMAR.

SUBLIMATE, a chemical preparation, consisting of quicksilver united with muriatic acid. See MERCURY, CHEMISTRY *Index*.

SUBLIMATION, in *Chemistry*, the condensing and collecting, in a solid form, by means of vessels aptly constructed, the fumes of bodies raised from them by the application of a proper heat.

SUBLIME, or SUBLIMITY. See the article GRANDEUR and SUBLIMITY.

SUBLINGUAL ARTERY. See ANATOMY.

SUBLINGUAL Glands, in *Anatomy*, two glands under the tongue, placed one on each side thereof.

SUBMULTIPLE, in *Geometry*, &c. A submultiple number, or quantity, is that which is contained a certain number of times in another, and which, therefore, repeated a certain number of times, becomes exactly equal thereto. Thus 3 is a submultiple of 21. In which sense a submultiple coincides with an aliquot part.

SUBMULTIPLE Ratio, is that between the quantity contained and the quantity containing. Thus the ratio of 3 to 21 is submultiple. In both cases submultiple is the reverse of multiple: 21, *e. gr.* being a multiple of 3, and the ratio of 21 to 3 a multiple ratio.

SUBORDINARIES. See HERALDRY, Chap. III. Sect. II.

SUBORDINATION, a relative term, expressing an inferiority betwixt one person and another.

SUBORNATION, in *Law*, a secret, underhand, preparing, instructing, or bringing in a false witness; and from hence *subornation of perjury* is the preparing or corrupt alluring to perjury. The punishment for this crime was formerly death, then banishment or cutting out the tongue, afterwards forfeitures of goods; and it is now a fine and imprisonment, and never more to be received as evidence. The statute 2 Geo. II. c. 25. superadded a power for the court to order the offender to be sent to the house of correction for a term not exceeding seven years, or be transported for the same period.

SUBPOENA, in *Law*, a writ whereby common persons are called into chancery, in such cases where the common law hath provided an ordinary remedy; and the name of it proceeds from the words therein, which charge the party called to appear at the day and place affirmed, *sub pœna centum librarum*, &c. The subpœna is the leading process in the courts of equity; and by statute, when a bill is filed against any person, process of subpœna shall be taken out to oblige the defendant to appear and answer the bill, &c.

SUBPOENA ad testificandum, a writ or process to bring in witnesses to give their testimony. If a witness on being served with this process does not appear, the court will issue an attachment against him; or a party, plaintiff or defendant, injured by his non-attendance, may maintain an action against the witness. See *Blackst. Com.* vol. viii. p. 369.

SUBPOENA, in *Equity*, a process in equity, calling on a defendant to appear and answer to the complainant's bill. See statute 5th Geo. II. c. 25. which enacts, that where the party cannot be found to be served with a subpœna, and absconds (as is believed) to avoid being served, a day shall be appointed him to appear to the bill of the plaintiff; which is to be inserted in the London Gazette, read in the parish church where the defendant last lived, and fixed up at the Royal Exchange: and if the defendant doth not appear upon that day, the bill shall be taken *pro confesso*.

SURREPTITIOUS, a term applied to a letter, licence, patent, or other act, fraudulently obtained of a superior, by concealing some truth which, had it been known, would have prevented the concession or grant.

SUBROGATION, or SURROGATION, in the civil law, the act of substituting a person in the place, and intitling him to the rights, of another. In its general sense, subrogation implies a succession of any kind, whether of a person to a person, or of a person to a thing.

There are two kinds of subrogation: the one *conventional*, the other *legal*. *Conventional* subrogation is a contract whereby a creditor transfers his debt, with all appurtenances thereof, to the profit of a third person. *Legal* subrogation is that which the law makes in favour of a person who discharges an antecedent creditor; in which case there is a legal translation of all rights of the ancient creditor to the person of the new one.

SUBSCRIPTION, in general, signifies the signature put at the bottom of a letter, writing, or instrument.

In commerce, it is used for the share or interest which particular persons take in a public stock or a trading company, by writing their names, and the shares they require, in the books or register thereof.

SUBSCRIPTION to articles of faith is required of the clergy of every established church, and of some churches not established. Whether such subscription serves any good purpose, in a religious or theological view, is a very doubtful question. It may be necessary in an establishment, as a test of loyalty to the prince, and of attachment to the constitution, civil and ecclesiastical, but it cannot produce

produce uniformity of opinion. As all language is more or leſs ambiguous, it becomes difficult, if not impoſſible, to determine in what ſenſe the words of long eſtabliſhed creeds are to be interpreted; and we believe that the clergy of the churches of England and Scotland ſeldom conſider themſelves as fettered by the Thirty-nine Articles, or the Confeſſion of Faith, when compoſing inſtructions either for their reſpective pariſhes or for the public at large. See INDEPENDENTS.

SUBSCRIPTION, in the commerce of books, ſignifies an engagement to take a certain number of copies of a book, intended to be printed, and a reciprocal obligation of the bookſeller or publiſher to deliver the ſaid copies, on certain terms. Theſe ſubſcriptions, which had their riſe in England about the middle of the 17th century, were lately very frequent in France and Holland, and are now very common among ourſelves.

SUBSEQUENT, ſomething that comes after another, particularly with regard to the order of time.

SUBSIDY, in *Law*, ſignifies an aid or tax granted to the king by parliament, for the neceſſary occaſions of the kingdom; and is to be levied on every ſubject of ability, according to the rate or value of his lands or goods: but this word, in ſome of our ſtatutes, is confounded with that of cuſtoms. See TAX.

SUBSTANCE, the ſubjects to which we ſuppoſe qualities belong. Thus gold is the ſubſtance to which the qualities of ductility, yellowneſs, denſity, &c. belong. See METAPHYSICS, n° 145.

SUBSTANTIAL, in the ſchools, ſomething belonging to the nature of ſubſtance.

SUBSTANTIVE, in *Grammar*. See GRAMMAR.

SUBSTITUTE, a perſon who officiates for another in his abſence.

SUBSTITUTION, in the *Civil Law*, a diſpoſition of a teſtament, whereby the teſtator ſubſtitutes one heir for another, who has only the uſufruct, and not the property or the thing, left him.

SUBSTRACTION, or SUBTRACTION, in *Arithmetic*, the ſecond rule, or rather operation, in arithmetic, whereby we deduct a leſs number from a greater, to learn their preciſe difference. See ARITHMETIC and ALGEBRA.

SUBTANGENT OF A CURVE, the line that determines the interſection of a tangent with the axis; or that determines the point wherein the tangent cuts the axis prolonged.

SUBTENSE, formed from *ſub* "under," and *tendo* "I ſtretch," in *Geometry*, a right line which is oppoſite to an angle, and drawn between the two extremities of the arch which meaſures that angle.

SUBTERRANEOUS, whatever is under ground: thus naturaliſts ſpeak of ſubterraneous fires, ſubterraneous damps, &c.

SUBTERRANEOUS Cavern. See QUARRIES.

SUBTILE, in *Phyſics*, an appellation given to whatever is extremely ſmall, fine, and delicate; ſuch as the animal ſpirits, the effluvia of odorous bodies, &c. are ſuppoſed to be.

SUBULARIA, ROUGH-LEAVED ALYSSON, or *Awlwort*, a genus of plants belonging to the claſs tetradynamia, and in the natural order ranging under the 39th order, *ſiliquoſæ*. See BOTANY *Index*.

SUBULATED, ſomething ſhaped like an awl.

SUCCEDANEUM, in *Pharmacy*, denotes a drug ſubſtituted in the place of another.

SUCCESSION, in *Metaphyſics*, the idea which we get by reflecting on the ideas that follow one another in our mind; and from the ſucceſſion of ideas we get the idea of *time*. See METAPHYSICS, N° 93. and 209.

SUCCESSION, in *Law*. See DESCENT.

SUCCESSION to the Crown. See *HEREDITARY Right*.—From the days of Egbert, the firſt ſole monarch of England, even to the preſent, the four cardinal maxims mentioned in that article have ever been held conſtitutional canons of ſucceſſion. It is true, as Sir William Blackſtone obſerves, this ſucceſſion, through fraud or force, or ſometimes through neceſſity, when in hoſtile times the crown deſcended on a minor or the like, has been very frequently ſuſpended; but has generally at laſt returned back into the old hereditary channel, though ſometimes a very conſiderable period has intervened. And even in thoſe inſtances where this ſucceſſion has been violated, the crown has ever been looked upon as hereditary in the wearer of it. Of which the uſurpers themſelves were ſo ſenſible, that they for the moſt part endeavoured to vamp up ſome feeble ſhow of a title by deſcent, in order to amuſe the people, while they gained the poſſeſſion of the kingdom. And, when poſſeſſion was once gained, they conſidered it as the purchaſe or acquiſition of a new eſtate of inheritance, and tranſmitted, or endeavoured to tranſmit it, to their own poſterity by a kind of hereditary right of uſurpation. (See Black. Com. vol. i. 197—217.). From the hiſtorical view there given, it appears that the title to the crown is at preſent hereditary, though not quite ſo abſolutely hereditary as formerly: and the common ſtock or anceſtor, from whom the deſcent muſt be derived, is alſo different. Formerly the common ſtock was King Egbert; then William the Conqueror; afterwards, in James I.'s time, the two common ſtocks united; and ſo continued till the vacancy of the throne in 1688: now it is the Princeſs Sophia in whom the inheritance was veſted by the new king and parliament. Formerly, the deſcent was abſolute, and the crown went to the heir without any reſtriction: but now, upon the new ſettlement, the inheritance is conditional: being limited to ſuch heirs only, of the body of the Princeſs Sophia, as are Proteſtant members of the church of England, and are married to none but Proteſtants.

And in this due medium conſiſts the true conſtitutional notion of the right of ſucceſſion to the imperial crown of theſe kingdoms. The extremes between which it ſteers are each of them equally deſtructive of thoſe ends for which ſocieties were formed and kept on foot. Where the magiſtrate, upon every ſucceſſion, is elected by the people, and may by the expreſs proviſion of the laws be depoſed (if not puniſhed) by his ſubjects, this may ſound like the perfection of liberty, and look well enough when delineated on paper; but in practice will be ever productive of tumult, contention, and anarchy. And, on the other hand, divine indefeaſible hereditary right, when coupled with the doctrine of unlimited paſſive obedience, is ſurely of all conſtitutions the moſt thoroughly ſlaviſh and dreadful. But when ſuch an hereditary right as our laws have created and veſted in the royal ſtock, is cloſely interwoven with thoſe liberties which are equally the inheritance of the ſubject; this union

union will form a conſtitution, in theory the moſt beautiful of any, in practice the moſt approved, and, we truſt, in duration the moſt permanent.

In France the ſucceſſion to the monarchy was limited to heirs male (ſee SALIC); but in Navarre the crown was inherited by the heir of line, whether male or female. The caſe ſtands thus: Philip the Fourth, king of France, ſurnamed *the Fair*, in the year 1285 eſpouſed Jane queen of Navarre in her own right; and as king conſort of this latter kingdom added the title of Navarre to his former one of France. Louis X. ſon and heir of Philip and Jane (ſurnamed *Hutin* or the *Boiſterous*), ſucceeded to both crowns. By Margaret his firſt wife, who had been crowned queen of Navarre, he left one daughter, Joan or Jane. His ſecond wife Clementina was pregnant at the time of his deceaſe, and was delivered of a poſthumous ſon, whom moſt of the French annaliſts recognize as John I. of France, though he lived no longer than three weeks. On his death the kingdom of France paſſed to Philip V. (ſurnamed *the Long*), and that of Navarre (to which the Salic law could by no conſtruction extend) to Joanna the only child and heir of Louis and Margaret. From Joanna, in lineal ſucceſſion, the kingdom of Navarre paſſed to Jane d'Albret, mother of Henry IV. of France, and wife of Anthony of Vendoſme, who as king conſort wore the crown of Navarre. On the acceſſion of Henry to the kingdom of France, the two monarchies were united, and the four ſucceeding princes aſſumed the joint titles.

SUCCINIC ACID, an acid extracted from amber by ſublimation in a gentle heat, and which riſes in a concrete form into the neck of the ſubliming veſſel. See CHEMISTRY *Index*.

SUCCINUM, AMBER, in *Mineralogy*, a ſpecies of bitumen claſſed under the inflammable ſubſtances. See MINERALOGY *Index*.

SUCCORY. See CICHORIUM, BOTANY *Index*.

SUCCOTH, in *Ancient Geography*, a town which lay between the brook Jabbok and the river Jordan, where Jacob fixed his tents. There was another Succoth, where the Iſraelites firſt encamped after their departure from Rameſes towards the Red ſea. Succoth ſignifies *tents*.

SUCCUBUS, a term uſed by ſome writers for a dæmon who aſſumes the ſhape of a woman, and as ſuch lies with a man; in which ſenſe it ſtands oppoſed to *incubus*, which was a dæmon in form of a man, that lies with a woman. But the truth is, the ſuccubus is only a ſpecies of the nightmare. See MEDICINE, N° 329.

SUCCULA, in *Mechanics*, an axis or cylinder, with ſtaves in it to move it round; but without any tympanum or peritrochium.

SUCCULENT PLANTS, among botaniſts, ſuch whoſe leaves are thick and full of juice.

SUCKER. See CYCLOPTERUS, ICHTHYOLOGY *Index*.

SUCKERS, in *Gardening*, the ſame with OFFSETS.

SUCKING-FISH. See ECHENEIS, ICHTHYOLOGY *Index*.

SUCKLING, SIR JOHN, an Engliſh poet and dramatic writer, was the ſon of Sir John Suckling, comptroller of the houſehold to King Charles I. and born at Witham in Eſſex in 1613. He diſcovered an uncommon propenſity to the acquiring of languages, inſomuch that he is reported to have ſpoken Latin at five years of age, and to have written it at nine. When he grew up, he travelled; but ſeems to have affected nothing more than the character of a courtier and fine gentleman; which he ſo far attained, that he was allowed to have the peculiar happineſs of making every thing he did become him. In his travels he made a campaign under the great Guſtavus Adolphus; and his loyalty, if not his valour, appeared in the beginning of our civil wars; for, after his return to England, he raiſed a troop of horſe for the king's ſervice entirely at his own charge; and mounted them ſo completely and richly, that they are ſaid to have coſt him 12,000l. This troop, with Sir John at its head, behaved ſo ill in the engagement with the Scots, upon the Engliſh borders, in 1639, as to occaſion the famous lampoon compoſed by Sir John Mennis; " Sir John he got him an ambling nag," &c. This ballad, which was ſet to a briſk tune, was much ſung by the parliamentarians, and continues to be ſung to this day. This diſaſtrous expedition, and the ridicule that attended it, was ſuppoſed to have haſtened his death; being ſeized by a fever, of which he died, at 28 years of age. He was a ſprightly wit, and an eaſy verſifier, but no great poet. His works, conſiſting of a few poems, letters, and plays, have nevertheleſs gone through ſeveral editions.

SUCTION, the act of ſucking or drawing up a fluid, as air, water, milk, or the like, by means of the mouth and lungs; or, in a ſimilar manner, by artificial means. See PNEUMATICS and HYDRODYNAMICS.

SUDATORY, a name given by the ancient Romans to their hot or ſweating rooms; ſometimes alſo called *Laconica*.

SUDEROE. See *FERRO-Iſlands*.

SUDORIFIC, an appellation given to any medicine that cauſes or promotes ſweat.

SUESSIONES, a branch of the Remi, a people of Gallia Belgica (Pliny); called ſometimes *Sueſſones*, in the lower age *Sueſſi*; ſituated between the Remi to the eaſt, the Nervii to the north, the Veromandui to the weſt, and the Meldæ to the ſouth, in the tract now called *le Soiſſonois*.—*Sueſſiones*, *Sueſſones*, and *Sueſſonæ*, the name of their city in the lower age; thought to have been formerly called *Noviodunum* (Cæſar), is now called *Soiſſons*.

SUET, SEVUM, or *Sebum*, in *Anatomy*, the ſolid fat found in ſeveral animals, as ſheep, oxen, &c. but not in the human ſpecies. See the article FAT.—It is of the ſevum that tallow is made.

SUETONIUS TRANQUILLUS, CAIUS, a famous Latin hiſtorian, was born at Rome, and became ſecretary to the emperor Adrian, about the 118th year of the Chriſtian era; but that poſt was taken from him three years after, when ſeveral perſons fell under that prince's diſpleaſure for not ſhowing the empreſs Sabina all the reſpect ſhe deſerved. During his diſgrace he compoſed many works, which are loſt. Thoſe now extant are his Hiſtory of the XII firſt Emperors, and a part of his treatiſe of the Illuſtrious Grammarians and Rhetoricians. Pliny the Younger was his intimate friend, and perſuaded him to publiſh his books. His Hiſtory of the XII Roman Emperors has been much commended by moſt of our polite ſcholars. He repreſents, in a continued ſeries of curious and intereſting particulars, without any digreſſions or reflections, the actions of the emperors, without omitting their vices, which he expoſes with all their deformity, and with the fame freedom mentions the good qualities of the very fame perfons; but the horrid diffolutenefs and obfcene actions he relates of Tiberius, Caligula, Nero, &c. have made fome fay, that he wrote the lives of the emperors with the fame licentioufnefs with which they lived. The edition of this hiftory procured by Grævius at Utrecht in 1672, with the excellent Commentaries of Torrentius and Cafaubon, and the notes of fome other learned critics, is much efteemed. Burman alfo publifhed an edition in 2 vols. 4to, with notes.

SUEVI, the Catti or Chatti of Cæfar (Strabo), placed on the Rhine: the reafon of Cæfar's calling them thus does not appear, though confiderably diftant from the proper Suevi or Alemanni.

SUEVI, (Tacitus), a common name of the people fituated between the Elbe and the Viftula, diftinguifhed otherwife by particular names; as in Ptolemy, *Suevi Angeli*, *Suevi Sennones*.

SUEVUS, in *Ancient Geography*, a river of Germany, thought to be the fame with the Viadrus or Oder, emptying itfelf at three mouths into the Baltic, the middlemoft of which is called *Swine* or *Swene;* which laft comes nearer the name *Suevus*.

SUEZ, a fmall fea-port town, fituated near the northern extremity of the Red fea, and about 30 hours journey eaft from Cairo. The country around it is a fandy plain, without the fmalleft fpot of verdure. The only water which can be drunk is brought from El-Naba, or the fpring, at the diftance of three hours journey; and it is fo brackifh, that without a mixture of rum it is infupportable to Europeans. The town itfelf is a collection of miferable ruins, the khans being the only folid buildings; yet from March till June, the feafon when the Jidda and Yambo fleet arrives, the town becomes crowded; but after its departure nobody remains except the governor, who is a Mamlouk, 12 or 14 perfons who form his houfehold, and the garrifon. The fortrefs is a defencelefs heap of ruins, which the Arabs confider as a citadel, becaufe it contains fix brafs fourpounders, and two Greek gunners, who turn their heads afide when they fire. The harbour is a wretched quay, where the fmalleft boats are unable to reach the fhore, except at the higheft tides. There, however, the merchandife is embarked, to convey it over the banks of fand to the veffels which anchor in the road. This road, fituated a league from the town, is feparated from it by a fhore which is left dry at low water; it has no works for its defence, fo that the veffels which M. Volney tells us he has feen there, to the number of 28 at a time, might be attacked without oppofition; for the fhips themfelves are incapable of refiftance, none having any other artillery than four rufty fwivels.

Volney's Travels, vol. i.

Suez has always been, notwithftanding its local difadvantages, a place of great trade, on account of its geographical fituation. It was by the gulf of Suez that the commodities of India were formerly conveyed to Europe, till the difcovery of the paffage by the Cape of Good Hope converted that trade into a new channel. As the ifthmus of Suez, which feparates the Red fea from the Mediterranean, is not more than 57 miles, it has been frequently propofed to join thefe two feas together by a canal. As there are no mountains nor remarkable inequalities of furface, this plan would at firft view appear eafy to be executed. But though the difference of levels would not prevent a junction, the great difficulty arifes from the nature of the correfponding coafts of the Mediterranean and the Red fea, which are of a low and fandy foil, where the waters form lakes, fhoals, and moraffes, fo that veffels cannot approach within a confiderable diftance. It will therefore be found fcarcely poffible to dig a permanent canal amid thefe fhifting fands: not to mention, that the fhore is deftitute of harbours, which muft be entirely the work of art. The country befides has not a drop of frefh water, and to fupply the inhabitants, it muft be brought as far as from the Nile.

The beft and only method therefore of effecting this junction, is that which has been already fuccefsfully practifed at different times; which is, by making the river itfelf the medium of communication, for which the ground is perfectly well calculated; for Mount Mokattum fuddenly terminating in the latitude of Cairo, forms only a low and femicircular mound, round which is a continued plain from the banks of the Nile as far as the point of the Red fea. The ancients, who early underftood the advantage to be derived from this fituation, adopted the idea of joining the two feas by a canal connected with the river. Strabo * obferves, that this was firft executed under Sefoftris, who reigned about the time of the Trojan war; and this work was fo confiderable as to occafion it to be remarked, "that it was 100 cubits (or 170 feet) wide, and deep enough for large veffels." After the Greeks conquered the country, it was reftored by the Ptolemies, and again renewed by Trajan. In fhort, even the Arabs themfelves followed thefe examples. "In the time of Omar ebn-el-Kattab (fays the hiftorian El Makin), the cities of Mecca and Medina fuffering from famine, the caliph ordered Amrou governor of Egypt to cut a canal from the Nile to Kolzoum, that the contributions of corn and barley appointed for Arabia might be conveyed that way."

* Lib. xvii.

This canal is the fame which runs at prefent to Cairo, and lofes itfelf in the country to the north-eaft of Berket-el-Hadj, or the Lake of the Pilgrims.

The place on the weft coaft of the gulf of Suez, where the children of Ifrael are fuppofed to have entered it, is called *Badea*, about fix miles to the north of Cape Korondel, on the other fide of the gulf, as we are informed in a letter from the ingenious Edward Wortley Montague, F. R. S. to Dr Watfon, containing an account of his journey from Cairo to the Written Mountains in the defert of Sinai. Oppofite to Badea is a ftrong current which fets to the oppofite fhore, about fouth-eaft, with a whirlpool called *Birque Pharaone*, the *well* or *pool of Pharaoh*, being the place where his hoft is faid to have been deftroyed. We are told by the fame gentleman, that the Egyptian fhore from Suez to Badea is fo rocky and fteep, that there was no entering upon the gulf but at one of thefe two places.

The Britifh nation, we believe, never attempted to carry on commerce with any of the ports of the Red fea beyond Jidda, till, on the fuggeftion of Mr Bruce, in 1776, fome Britifh merchants at Bengal equipped two or three veffels for Suez, laden with piece-goods of Bengal and coaft manufactures. The command of the veffels was committed to Captain Greig, a meritorious feaman; and the management of the goods was entrufted to Mr Shaw, a gentleman diftinguifhed for his mercantile knowledge. The fale turned out to advantage; but fuch

fuch great expences were incurred in making prefents to the bey of Cairo and Suez, as to confume the whole profits gained by the fale of the cargo. The great purpofe of the expedition was, however, accomplifhed, as a firman was obtained from the government of Cairo to trade by the way of Suez. In confequence of this, three fhips went to Suez the following year, and as many in 1778. The opening of this trade alarmed the jealoufy of the Eaft India Company; they applied to our government, and orders were given to relinquifh this promifing commerce. Thefe orders reached Egypt fooner than Bengal, and the confequence was fatal to the unfortunate adventurers who vifited Suez that year (1779). By a plan concerted between the beys, a large body of Bedouin Arabs attacked the caravan paffing from Suez to Cairo with goods valued at 12 lacks of rupees. The goods were plundered, the Europeans were ftripped and left naked in the defert, expofed to the burning rays of the fun, without a drop of water to quench their thirft, or food to fupport life. Moft of them died, and fome of their bodies were afterwards found mangled and disfigured by wolves. We have been favoured with a particular account of the fufferings of our countrymen by a correfpondent, which, we are forry, we have not room to infert. Thofe who wifh to obtain a more full account may confult the Annual Regifter for 1781 or 1782.

SUFFETULA, in *Ancient Geography*, a town of Africa, in the dominions of Carthage; probably fo called from Suffetes, the title of the magiftrates of that city. It is now called *Spaitla*, in the kingdom of Tunis, and has many elegant remains of antiquity. There are three temples in a great meafure entire; one of them of the Compofite order, the other two Corinthian. "A beautiful and perfect capital of the Compofite order (fays Mr Bruce), the only perfect one that now exifts, is defigned in all its parts in a very large fize; and with the detail of the reft of the ruin, is a precious monument of what that order was, now in the collection of the king." The town itfelf (he fays) is fituated in the moft beautiful fpot in Barbary, furrounded by great numbers of juniper-trees, and watered by a pleafant ftream, which finks under the earth at that place, without appearing any more.

SUFFOCATION, the privation of the function of refpiration or breathing. See the articles DROWNING, HANGING, &c.

SUFFOLK, a county of England. Its name is contracted from *Southfolk*, fo called from its fituation in regard to Norfolk. It is bounded on the weft by Cambridge-fhire; on the fouth by Effex, from which it is parted by the river Stour; on the eaft by the German ocean; and on the north by Norfolk, feparated from it by the Leffer Oufe and the Waveney. From weft to eaft it is 52 miles in length, about 20 at a medium in breadth, and 196 in circumference. It contains 22 hundreds, 29 market-towns, 575 parifhes, upwards of 34,000 houfes, and 210,431 inhabitants. The whole is divided into two parts, viz. the Liberty of St Edmund, and the Geldable; the former of which contains the weft parts of the county, and the other the eaft; and there is a grand jury for each at the affizes. The air is reckoned as wholefome and pleafant as any in the kingdom, nor is it otherwife upon the fea coaft, which is dry and fandy, and free from falt marfhes. The foil, except to the weft and upon the fea-coaft, is very rich, being a compound of clay and marle. Towards the fea there are large heaths and tracts of fand; but thefe produce hemp, rye, and peafe, and feed great flocks of fheep. About Newmarket the foil is much the fame; but in high Suffolk or the woodlands, befides wood, there are very rich paftures, where abundance of cattle are fed. In other parts of the county, as about Bury, there is plenty of corn. As this county is noted for the richnefs of its paftures, fo is it for butter and cheefe, efpecially the former, which is faid to be remarkably good; fo that being packed up in firkins, it is fold for all ufes both by fea and land, and conveyed to many parts of England, efpecially to London. The inland parts of the county are well fupplied with wood for fuel, and thofe upon the fea-coaft with coals from Newcaftle. The manufactures of the county are chiefly woollen and linen cloth. It lies in the diocefe of Norwich, has two archdeacons, viz. of Sedbury and Suffolk; gives title of earl to a branch of the Howards; fends two members to parliament for the county, and two for each of the following places, Ipfwich, Dunwich, Orford, Aldborough, Sudbury, Eye, and St Edmund's-Bury. The county is extremely well watered by the following rivers, which either traverfe its borders, or run acrofs into the German ocean, viz. the Leffer Oufe, the Waveney, the Blithe, the Deben, the Orwell or Gipping, and the Stour.

Gough's edition of Camden's Britannia.

SUFFRAGAN, an appellation given to fimple bifhops with regard to archbifhops, on whom they depend, and to whom appeals lie from the bifhops courts.

Suffragan is likewife the appellation given to a bifhop, who is occafionally appointed to refide in a town or village, and affift the diocefan.

SUFFRAGE, denotes a vote given in an affembly, where fomething is deliberated on, or where a perfon is elected to an office or benefice.

SUFFRUTEX, among botanifts, denotes an underfhrub, or the loweft kind of woody plants, as lavender.

SUGAR, a folid fweet fubftance obtained from the juice of the fugar-cane; or, according to chemifts, an effential falt, capable of cryftallization, of a fweet and agreeable flavour, and contained in a greater or lefs quantity in almoft every fpecies of vegetables, but moft abundant in the fugar-cane.

1 Value of fugar.

As the fugar-cane is the principal production of the Weft Indies, and the great fource of their riches; as it is fo important in a commercial view, from the employment which it gives to feamen, and the wealth which it opens for merchants; and befides now is become a neceffary of life—it may juftly be efteemed one of the moft valuable plants in the world. The quantity confumed in Europe is eftimated at nine millions fterling, and the demand would probably be greater if it could be fold at a reduced price. Since fugar then is reckoned fo precious a commodity, it muft be an object of defire to all perfons of curiofity and refearch, to obtain fome general knowledge of the hiftory and nature of the plant by which it is produced, as well as to underftand the procefs by which the juice is extracted and refined. We will therefore firft inquire in what countries it originally flourifhed, and when it was brought into general ufe, and became an article of commerce.

From the few remains of the Grecian and Roman authors which have furvived the ravages of time, we can find no proofs that the juice of the fugar-cane was known

Sugar.

2 was probably known to the ancient Jews.

at a very early period. There can be no doubt, however, that in thoſe countries where it was indigenous its value was not long concealed. It is not improbable that it was known to the ancient Jews; for there is ſome reaſon to ſuppoſe, that the Hebrew word קנה, which occurs frequently in the Old Teſtament, and is by our tranſlators rendered ſometimes *calamus* and ſometimes *ſweet-cane*, does in fact mean the ſugar-cane. The firſt paſſage in which we have obſerved it mentioned is Exod. xxx. 23. where Moſes is commanded to make an ointment with myrrh, cinnamon, kené, and caſſia. Now the kené does not appear to have been a native of Egypt nor of Judea; for in Jeremiah vi. 20. it is mentioned as coming from a far country. "To what purpoſe cometh there to me incenſe from Sheba and the ſweet-cane from a far country?" This is not true of the calamus aromaticus, which grows ſpontaneouſly in the Levant, as well as in many parts of Europe. If the cinnamon mentioned in the paſſage of Exodus quoted above was true cinnamon, it muſt have come from the Eaſt Indies, the only country in the world from which cinnamon is obtained. There is no difficulty therefore in ſuppoſing, that the ſugar-cane was exported from the ſame country. If any credit be due to etymology, it confirms the opinion that kené denotes the ſugar-cane; for the Latin word *canna* and the Engliſh word *cane* are evidently derived from it. It is alſo a curious fact, that *ſachar* or *ſhcker* *, in Hebrew, ſignifies *inebriation*, from which the Greek word σακχαρ, "ſugar," is undoubtedly to be traced.

3 Account of it by Greek and Roman authors.

* שכר.

The ſugar-cane was firſt made known to the weſtern parts of the world by the conqueſts of Alexander the Great. Strabo † relates that Nearchus his admiral found it in the Eaſt Indies in the year before Chriſt 325. It is evidently alluded to in a fragment of Theophraſtus, preſerved in Photius. Varro, who lived A. C. 68, deſcribes it in a fragment quoted by Iſidorus ‡ as a fluid preſſed from reeds of a large ſize, which was ſweeter than honey §. Dioſcorides, about the year 35 before Chriſt, ſays "that there is a kind of honey called *ſaccharon*, which is found in India and Arabia Felix. It has the appearance of ſalt, and is brittle when chewed. If diſſolved in water, it is beneficial to the bowels and ſtomach, is uſeful in diſeaſes of the bladder and kidneys, and, when ſprinkled on the eye, removes thoſe ſubſtances that obſcure the ſight." This is the firſt account we have of its medical qualities. Galen often preſcribed it as a medicine. Lucan relates, that an oriental nation in alliance with Pompey uſed the juice of the cane as a common drink.

Sugar.

4 Is a native of the Eaſt Indies.

That the ſugar-cane is an indigenous plant in ſome parts of the Eaſt Indies, we have the ſtrongeſt reaſon to believe; for Thunberg found it in Japan, and has accordingly mentioned it as a native of that country in his *Flora Japonica*, publiſhed in 1784. Oſbeck alſo found it in China in 1751. It may indeed have been tranſplanted from ſome other country; but as it does not appear from hiſtory that the inhabitants of Japan or China ever carried on any commerce with remote nations, it could only be conveyed from ſome neighbouring country. Marco Polo, a noble Venetian, who travelled into the eaſt about the year 1250, found ſugar in abundance in Bengal. Vaſco de Gama, who doubled the Cape of Good Hope in 1497, relates, that a conſiderable trade in ſugar was then carried on in the kingdom of Calicut. On the authority of Dioſcorides and Pliny, too, we ſhould be diſpoſed to admit, that it is a native of Arabia, did we not find, on conſulting Niebuhr's Travels, that that botaniſt has omitted it when enumerating the moſt valuable plants of that country. If it be a ſpontaneous production of Arabia, it muſt ſtill flouriſh in its native ſoil. Mr Bruce found it in Upper Egypt. If we may believe the relation of Giovan Lioni, a conſiderable trade was carried on in ſugar in Nubia in 1500: it abounded alſo at Thebes, on the Nile, and in the northern parts of Africa, about the ſame period.

5 Introduced into Europe probably during the cruſades.

There is reaſon to believe that the ſugar-cane was introduced into Europe during the cruſades; expeditions which however romantic in their plan, and unſucceſsful in their execution, were certainly productive of many advantages to the nations of Europe. Albertus Aquenſis, a monkiſh writer, obſerves, that the Chriſtian ſoldiers in the Holy Land frequently derived refreſhment and ſupport during a ſcarcity of proviſions by ſucking the canes. This plant flouriſhed alſo in the Morea, and in the iſlands of Rhodes and Malta; from which it was tranſported into Sicily. The date of this tranſaction it is not eaſy to aſcertain; but we are ſure that ſugar was cultivated in that iſland previous to the year 1166; for Lafitau the Jeſuit, who wrote a hiſtory of the Portugueſe diſcoveries, mentions a donation made that year to the monaſtery of St Bennet, by William the ſecond, king of Sicily, of a mill for grinding ſugar-canes, with all its rights, members, and appurtenances.

From Sicily, where the ſugar-cane ſtill flouriſhes on the ſides of Mount Hybla, it was conveyed to Spain, Madeira, the Canary and Cape de Verd iſlands, ſoon after they were diſcovered in the 15th century.

D'Orville's Travels.

6 Suppoſed by ſome not a native of America or the Weſt Indies.

An opinion has prevailed, that the ſugar-cane is not a native of the weſtern continent, or its adjacent iſlands the Weſt Indies, but was conveyed thither by the Spaniards or Portugueſe ſoon after the diſcovery of America by Columbus. From the teſtimony of Peter Martyr, in the third book of his firſt decade, compoſed during Columbus's ſecond voyage, which commenced in 1493 and ended in 1495, it appears, that the ſugar-cane was known at that time in Hiſpaniola. It may be ſaid, that it was brought thither by Columbus; but for this aſſertion we have found no direct evidence; and though we had

(A) For a more minute account of the hiſtory of ſugar in the early and middle ages, a paper of the Mancheſter Tranſactions, in Volume IV. by Dr Falconer, may be conſulted.

Sugar. had direct evidence, this would not prove that the ſugar-cane was not an indigenous plant of the Weſt Indies. There are authors of learning who, after inveſtigating this ſubject with attention, do not heſitate to maintain, that it is a native both of the iſlands and of the continent of America.

* Tom. iii. c. xv.

7 This opinion opposed by Labat.

P. Labat has ſupported this opinion with much appearance of truth *; and, in particular, he appeals to the teſtimony of Thomas Gage, an Engliſhman, who viſited New Spain in 1625. Gage enumerates ſugar-canes among the proviſions with which the Charaibes of Guadaloupe ſupplied his ſhip. "Now (ſays Labat) it is a fact that the Spaniards had never cultivated an inch of ground in the ſmaller Antilles. Their ſhips commonly touched at thoſe iſlands indeed for wood and water; and they left ſwine in the view of ſupplying with freſh proviſions ſuch of their countrymen as might call there in future; but it would be abſurd in the higheſt degree to ſuppoſe, that they would plant ſugar-canes, and at the ſame time put hogs aſhore to deſtroy them.

"Neither had the Spaniards any motive for beſtowing this plant on iſlands which they conſidered as of no kind of importance, except for the purpoſe that has been mentioned; and to ſuppoſe that the Charaibes might have cultivated, after their departure, a production of which they knew nothing, betrays a total ignorance of the Indian diſpoſition and character.

8 From teſtimony.

"But (continues Labat) we have ſurer teſtimony, and ſuch as proves, beyond all contradiction, that the ſugar-cane is the natural production of America. For, beſides the evidence of Francis Ximenes, who, in a Treatiſe on American Plants, printed at Mexico, aſſerts, that the ſugar-cane grows without cultivation, and to an extraordinary ſize, on the banks of the river Plate, we are aſſured by Jean de Lery, a Proteſtant miniſter, who was chaplain in 1556 to the Dutch garriſon in the fort of Coligny, on the river Janeiro, that he himſelf found ſugar-canes in great abundance in many places on the banks of that river, and in ſituations never viſited by the Portugueſe. Father Hennepen and other voyagers bear teſtimony in like manner to the growth of the cane near the mouth of the Miſſiſſippi; and Jean de Laet to its ſpontaneous production in the iſland of St Vincent. It is not for the plant itſelf, therefore, but for the ſecret of making ſugar from it, that the Weſt Indies are indebted to the Spaniards and Portugueſe; and theſe to the nations of the eaſt."

Such is the reaſoning of Labat, which the learned Lafitau has pronounced incontrovertible; and it is greatly ſtrengthened by recent diſcoveries, the ſugar-cane having been found in many of the iſlands of the Pacific ocean by our late illuſtrious navigator Captain Cook. Sugar.

9 Deſcription of the ſugar cane.

The ſugar-cane, or ſaccharum officinarum of botaniſts, is a jointed reed, commonly meaſuring (the flag part not included) from three feet and a half to ſeven feet in height, but ſometimes riſing to 12 feet. When ripe it is of a fine ſtraw colour inclining to yellow, producing leaves or blades, the edges of which are finely and ſharply ſerrated, and terminating in an arrow decorated with a panicle. The joints in one ſtalk are from 40 to 60 in number, and the ſtalks riſing from one root are ſometimes very numerous. The young ſhoot aſcends from the earth like the point of an arrow; the ſhaft of which ſoon breaks, and the two firſt leaves, which had been incloſed within a quadruple ſheath of ſeminal leaves, riſe to a conſiderable height (B).

10 Soil moſt favourable to its growth.

As the cane is a rank ſucculent plant, it muſt require a ſtrong deep ſoil to bring it to perfection, perhaps indeed no ſoil can be too rich for this purpoſe. The ſoil which experience has found to be moſt favourable to the cultivation of it in the Weſt Indies is the dark gray loam of St Chriſtopher's, which is ſo light and porous as to be penetrable by the ſlighteſt application of the hoe. The under ſtratum is gravel from 8 to 12 inches deep. Canes planted in particular ſpots in this iſland have been known to yield 8000 pounds of Muſcovado ſugar from a ſingle acre. The average produce of the iſland for a ſeries of years has been 16,000 hogſheads of 16 cwt. which is one-half only of the whole cane-land, or 8500 acres. When annually cut, it gives nearly two hogſheads of 16 cwt. per acre for the whole of the land in ripe canes.

Next to the aſhy loam of St Chriſtopher's is the ſoil which in Jamaica is called *brick-mould;* not as reſembling a brick in colour, but as containing ſuch a due mixture of clay and ſand as is ſuppoſed to render it well adapted for the uſe of the kiln. It is a deep, warm, and mellow, hazel earth, eaſily worked; and though its ſurface ſoon grows dry after rain, the under ſtratum retains a conſiderable degree of moiſture in the drieſt weather; with this advantage too, that even in the wetteſt ſeaſon it ſeldom requires trenching. Plant-canes, by which is meant canes of the firſt growth, have been known in very fine ſeaſons to yield two tons and a half of ſugar per acre. After this may be reckoned the black mould of ſeveral varieties. The beſt is the deep black earth of Barbadoes, Antigua, and ſome other of the windward iſlands; but there is a ſpecies of this mould in Jamaica that is but little, if any thing inferior to it, which abounds with limeſtone and flint on a ſubſtratum of ſoapy marle. Black mould on clay is more common; but

Edward's Hiſtory of the Weſt Indies, vol. ii.

(B) "A field of canes, when ſtanding, in the month of November, when it is in arrow or full bloſſom (ſays Mr Beckford in his deſcriptive Account of the Iſland of Jamaica), is one of the moſt beautiful productions that the pen or pencil can poſſibly deſcribe. It in common riſes from three to eight feet or more in height; a difference of growth that very ſtrongly marks the difference of ſoil or the varieties of culture. It is when ripe of a bright and golden yellow; and where obvious to the ſun, is in many parts very beautifully ſtreaked with red: the top is of a darkiſh green; but the more dry it becomes, from either an exceſs of ripeneſs or a continuance of drought, of a ruſſet yellow, with long and narrow leaves depending; from the centre of which ſhoots up an arrow like a ſilver wand from two to ſix feet in height; and from the ſummit of which grows out a plume of white feathers, which are delicately fringed with a lilac dye; and indeed is, in its appearance, not much unlike the tuft that adorns this particular and elegant tree."

but as the mould is generally ſhallow, and the clay ſtiff and retentive of water, this laſt ſort of land requires great labour, both in ploughing and trenching, to render it profitable. When manured and properly pulverized, it becomes very productive. It is unneceſſary to attempt a minute deſcription of all the other ſoils which are found in theſe iſlands. There is, however, a peculiar ſort of land on the north ſide of Jamaica, chiefly in the pariſh of Trelawney, that cannot be paſſed over unnoticed, not only on account of its ſcarcity but its value; few ſoils producing finer ſugars, or ſuch *as anſwer ſo well in the pan;* an expreſſion ſignifying a greater return of refined ſugar than common. The land alluded to is generally of a red colour; the ſhades of which, however, vary conſiderably from a deep chocolate to a rich ſcarlet; in ſome places it approaches to a bright yellow, but it is everywhere remarkable, when firſt turned up, for a gloſſy or ſhining ſurface, and if wetted ſtains the fingers like paint.

11 Proper ſeaſon for planting it.

As in every climate there is a ſeaſon more favourable for vegetation than others, it is of great importance that plants for ſeed be committed to the ground at the commencement of this ſeaſon. As the cane requires a great deal of moiſture to bring it to maturity, the propereſt ſeaſon for planting it is in the months of September and October, when the autumnal rains commence, that it may be ſufficiently luxuriant to ſhade the ground before the dry weather ſets in. Thus the root is kept moiſt, and the crop is ripe for the mill in the beginning of the enſuing year. Canes planted in the month of November, or later in the ſeaſon, loſe the advantage of the autumnal rains; and it often happens that dry weather in the beginning of the enſuing year retards their vegetation until the vernal or May rains ſet in, when they ſprout both at the roots and the joints; ſo that by the time they are cut the field is loaded with unripe ſuckers inſtead of ſugar-canes. A January plant, however, commonly turns out well; but canes planted very late in the ſpring, though they have the benefit of the May rains, ſeldom anſwer expectation; for they generally come in unſeaſonably, and throw the enſuing crops out of regular rotation. They are therefore frequently cut before they are ripe; or if the autumnal ſeaſon ſets in early, are cut in wet weather, which has probably occaſioned them to ſpring afreſh; in either caſe the effect is the ſame: The juice is unconcocted, and all the ſap being in motion, the root is deprived of its natural nouriſhment, to the great injury of the ratoon. The chief objection to a fall plant is this, that the canes become rank and top-heavy, at a period when violent rains and high winds are expected, and are therefore frequently lodged before they are fit to be cut.

12 Method of planting

The ſugar-cane is propagated by the top-ſhoots, which are cut from the tops of the old canes. The uſual method of planting in the Weſt Indies is this: The quantity of land intended to be planted, being cleared of weeds and other incumbrances, is firſt divided into ſeveral plats of certain dimenſions, commonly from 15 to 20 acres each; the ſpaces between each plat or diviſion are left wide enough for roads, for the conveniency of carting, and are called *intervals*. Each plat is then ſubdivided, by means of a line and wooden pegs, into ſmall ſquares of about three feet and a half. Sometimes indeed the ſquares are a foot larger; but this circumſtance makes but little difference. The negroes are then placed in a row in the firſt line, one to a ſquare, and directed to dig out with their hoes the ſeveral ſquares, commonly to the depth of five or ſix inches. The mould which is dug up being formed into a bank at the lower ſide, the excavation or cane-hole ſeldom exceeds 15 inches in width at the bottom, and two feet and a half at the top. The negroes then fall back to the next line, and proceed as before. Thus the ſeveral ſquares between each line are formed into a trench of much the ſame dimenſions with that which is made by the plough. An able negro will dig from 100 to 120 of theſe holes for his day's work of ten hours; but if the land has been previouſly ploughed and lain fallow, the ſame negro will dig nearly double the number in the ſame time (c).

The cane-holes or trench being now completed, whether by the plough or by the hoe, and the cuttings ſelected for planting, which are commonly the tops of the canes that have been ground for ſugar (each cutting containing five or ſix gems), two of them are ſufficient for a cane hole of the dimenſions deſcribed. Theſe, being placed longitudinally in the bottom of the hole, are covered with mould about two inches deep; the reſt of the bank being intended for future uſe. In 12 or 14 days the young ſprouts begin to appear; and as ſoon as they riſe a few inches above the ground, they are, or ought to be, carefully cleared of weeds, and furniſhed with an addition of mould from the banks. This is uſually performed by the hand. At the end of four or five months the banks are wholly levelled, and the ſpaces between the rows carefully hoe-ploughed. Frequent cleanings, while the canes are young, are indeed ſo eſſentially neceſſary, that no other merit in an overſeer can compenſate for the want of attention in this particular. A careful manager will remove at the ſame time all the lateral ſhoots or ſuckers that ſpring up after the canes begin to joint, as they ſeldom come to maturity, and draw nouriſhment from the original plants. 13 and cleaning it.

14 The plough might be uſed with advantage.

" In the cultivation of other lands, in Jamaica eſpecially (ſays Mr Edwards, the elegant hiſtorian of the Weſt Indies, whoſe ſuperior excellence has induced us frequently to refer to him in the courſe of this article), the plough has been introduced of late years, and in ſome few caſes to great advantage; but it is not every ſoil or ſituation that will admit the uſe of the plough; ſome lands being much too ſtony, and others too ſteep; and I am ſorry I have occaſion to remark, that a practice

(c) As the negroes work at this buſineſs very unequally, according to their different degrees of bodily ſtrength, it is ſometimes the practice to put two negroes to a ſingle ſquare; but if the land has not had the previous aſſiſtance of the plough, it commonly requires the labour of 50 able negroes for 13 days to hole 20 acres. In Jamaica, ſome gentlemen, to eaſe their own ſlaves, have this laborious part of the planting-buſineſs performed by job-work. The uſual price for holing and planting is 6l. currency per acre (equal to 4l. 7s. ſterling). The coſt of falling and clearing heavy wood-land is commonly as much more.

Sugar. tice commonly prevails in Jamaica, on properties where this auxiliary is used, which would exhaust the finest lands in the world. It is that of ploughing, then cross-ploughing, round-ridging, and harrowing the same lands from year to year, or at least every other year, without affording manure: accordingly it is found that this method is utterly destructive of the ratoon or second growth, and altogether ruinous. It is indeed astonishing that any planter of common reading or observation should be passive under so pernicious a system. Some gentlemen, however, of late manage better: their practice is to break up stiff and clayey land, by one or two ploughings, early in the spring, and give it a summer's fallow. In the autumn following, being then mellow and more easily worked, it is holed and planted by manual labour after the old method, which has been already described. But in truth, the only advantageous system of ploughing in the West Indies is to confine it to the simple operation of holing, which may certainly be performed with much greater facility and dispatch by the plough than by the hoe; and the relief which, in the case of stiff and dry soils, is thus given to the negroes, exceeds all estimation, in the mind of a humane and provident owner. On this subject I speak from practical knowledge. At a plantation of my own, the greatest part of the land which is annually planted is neatly and sufficiently laid into cane-holes, by the labour of one able man, three boys, and eight oxen, with the common single-wheeled plough. The ploughshare indeed is somewhat wider than usual; but this is the only difference, and the method of ploughing is the simplest possible. By returning the plough back along the furrow, the turf is alternately thrown to the right and to the left, forming a trench seven inches deep, about two feet and a half wide at the top, and one foot wide at the bottom. A space of 18 or 20 inches is left between each trench, on which the mould being thrown by the share, the banks are properly formed, and the holing is complete. Thus the land is not exhausted by being too much exposed to the sun; and in this manner a field of 20 acres is holed with one plough, and with great ease, in 13 days. The plants are afterwards placed in the trench as in the common method, where manual labour alone is employed.

Edwards's History of the West Indies, vol. ii.

In most parts of the West Indies it is usual to hole and plant a certain proportion of the cane-land, commonly one-third, in annual rotation. Canes of the first year's growth are called *plant canes*, as has been already observed. The spouts that spring from the roots of the canes that have been previously cut for sugar are called *ratoons*; the first yearly returns from their roots are called *first ratoons*; the second year's growth *second ratoons*.

13 Canes named according to the age of their roots.

16 Manures employed.

Mr Edwards informs us, that the manure generally used is a compost formed, 1st, Of the vegetable ashes drawn from the fires of the boiling and still houses. 2dly, Feculencies discharged from the still house, mixed up with rubbish of buildings, white-lime, &c. 3dly, Refuse, or field-trash (*i. e.*), the decayed leaves and stems of the canes; so called in contradistinction to cane-trash, reserved for fuel. 4thly, Dung, obtained from the horse and mule stables, and from moveable pens, or small inclosures made by posts and rails, occasionally shifted upon the lands intended to be planted, and into which the cattle are turned at night. 5thly, Good mould, collected from gullies and other waste places, and thrown into the cattle-pens.

17 The sugar-cane destroyed by monkeys,

The sugar-cane is liable to be destroyed by monkeys, rats, and insects. The upland plantations suffer greatly from monkeys; these creatures, which now abound in the mountainous parts of St Christopher's, were first brought thither by the French, when they possessed half that island; they come down from the rocks in silent parties by night, and having posted centinels to give the alarm if any thing approaches, they destroy incredible quantities of the cane, by their gambols as well as their greediness. It is in vain to set traps for these creatures, however baited; and the only way to protect the plantation, and destroy them, is to set a numerous watch, well armed with fowling-pieces, and furnished with dogs. The negroes will perform this service cheerfully, for they are very fond of monkeys as food. The celebrated Father Labat says, they are very delicious, but the white inhabitants of St Kitt's never eat them.

Grainger's History of the sugar-cane.

18 rats,

The low-land plantations suffer as much by rats as those on the mountains do from monkeys; but the rats, no more than the monkeys, are natives of the place; they came with the shipping from Europe, and breed in the ground under loose rocks and bushes: the field negroes eat them greedily, and they are said to be publicly sold in the markets at Jamaica. To free the plantations from these vermin, the breed of wild cats should be encouraged, and snakes suffered to multiply unmolested; they may also be poisoned with arsenic, and the rasped root of the cassava made into pellets, and plentifully scattered over the grounds. This practice, however, is dangerous; for as the rats when thus poisoned become exceeding thirsty, they run in droves to the neighbouring streams, which they poison as they drink, and the cattle grazing on the banks of these polluted waters have frequently perished by drinking after them: It is safer therefore to make the pellets of flour, kneaded with the juice of the nightshade, the scent of which will drive them away though they will not eat it. There is an East Indian animal called *mungoes*, which bears a natural antipathy to rats; if this animal was introduced into our sugar islands, it would probably extirpate the whole race of these noxious vermin. The *formica omnivora* of Linnæus, the carnivorous ant, which is called in Jamaica the *raffle's ant*, would soon clear a sugar plantation of rats.

19 and insects.

The sugar-cane is also subject to a disease which no foresight can obviate, and for which human wisdom has hitherto in vain attempted to find a remedy. This disease is called the *blast*, and is occasioned by a species of *aphis*. When this happens, the fine, broad, green blades become sickly, dry, and withered; soon after they appear stained in spots; and if these spots are carefully examined, they will be found to contain innumerable eggs of an insect like a bug, which are soon quickened, and cover the plants with the vermin: the juice of the canes thus affected becomes sour, and no future shoot issues from the joints. Ants also concur with the bugs to spoil the plantation, and against these evils it is hard to find a remedy.

20 Time at which the crop ripens

The crops of sugar-canes do not ripen precisely at the same period in all the colonies. In the Danish, Spanish, and Dutch settlements, they begin in January, and continue till October. This method does not imply any fixed season for the maturity of the sugar-cane. The plant, Raynal's Hiſtory of the Eaſt and Weſt Indies, vol. iv.

plant, however, like others, muſt have its progreſs; and it hath been juſtly obſerved to be in flower in the months of November and December. It muſt neceſſarily follow, from the cuſtom theſe nations have adopted of continuing to gather their crops for 10 months without intermiſſion, that they cut ſome canes which are not ripe enough, and others that are too ripe, and then the fruit hath not the requiſite qualities. The time of gathering them ſhould be at a fixed ſeaſon, and probably the months of March and April are the fitteſt for it; becauſe all the ſweet fruits are ripe at that time, while the ſour ones do not arrive at a ſtate of maturity till the months of July and Auguſt.

The Engliſh cut their canes in March and April; but they are not induced to do this on account of their ripeneſs. The drought that prevails in their iſlands renders the rains which fall in September neceſſary to their planting; and as the canes are 18 months in growing, this period always brings them to the preciſe point of maturity (D).

21
Seaſon of feſtivity.
Edwards, vol. iv. p. 226.

"The time of crop in the ſugar iſlands (ſays Mr Edwards) is the ſeaſon of gladneſs and feſtivity to man and beaſt. So palatable, ſalutary, and nouriſhing, is the juice of the cane, that every individual of the animal creation, drinking freely of it, derives health and vigour from its uſe. The meagre and ſickly among the negroes exhibit a ſurpriſing alteration in a few weeks after the mill is ſet in action. The labouring horſes, oxen, and mules, though almoſt conſtantly at work during this ſeaſon, yet, being indulged with plenty of the green tops of this noble plant, and ſome of the ſcummings from the boiling-houſe, improve more than at any other period of the year. Even the pigs and poultry fatten on the refuſe. In ſhort, on a well-regulated plantation, under a humane and benevolent director, there is ſuch an appearance during crop-time of plenty and buſy cheerfulneſs, as to ſoften, in a great meaſure, the hardſhips of ſlavery, and induce a ſpectator to hope, when the miſeries of life are repreſented as inſupportable, that they are ſometimes exaggerated through the medium of fancy."

22
The canes when cut are ſent to the mill.

The plants being cut, the branches at the top are given to the cattle for food; the top-ſhoot, which is full of eyes, is preſerved for planting. The canes are cut into pieces about a yard long, tied up in bundles, and carried in carts to the mill, where they are bruiſed, and the juice is extracted from them. The mill conſiſts principally of three upright iron-plated rollers or cylinders, from 30 to 40 inches in length, and from 20 to 25 inches in diameter; and the middle one, to which the moving power is applied, turns the other two by means of cogs. Between theſe rollers, the canes (being previouſly cut ſhort, and tied into bundles) are twice compreſſed; for having paſſed through the firſt and ſecond rollers, they are turned round the middle one by a circular piece of frame-work or ſcreen, called in Jamaica the *Dumb-returner*, and forced back through the ſecond and third; an operation which ſqueezes them completely dry, and ſometimes even reduces them to powder. The cane juice is received in a leaden bed, and thence conveyed into a veſſel called the *receiver*. The refuſe, or macerated rind of the cane (which is called *cane-traſh*, in contradiſtinction to *field-traſh*), ſerves for fuel to boil the liquor.

23
The juice extracted from them.

The juice as it flows from the mill, taken at a medium, contains eight parts of pure water, one part of ſugar, and one part conſiſting of coarſe oil and mucilaginous gum, with a portion of eſſential oil.

24
Veſſels uſed for purifying it are,

As this juice has a ſtrong diſpoſition to fermentation, it muſt be boiled as ſoon as poſſible. There are ſome water-mills that will grind with great eaſe canes ſufficient for 30 hogſheads of ſugar in a week. It is neceſſary to have boiling veſſels, or clarifiers, that will correſpond in dimenſions to the quantity of juice flowing from the receiver. Theſe clarifiers are commonly three in number, and are ſometimes capable of containing 1000 gallons each; but it is more uſual to ſee them of 300 or 400 gallons each. Beſides the clarifiers which are uſed for the firſt boiling, there are generally four coppers or boilers. The clarifiers are placed in the middle or at one end of the boiling-houſe. If at one end, the boiler called the *teache* is placed at the other, and ſeveral boilers (generally three) are ranged between them. The teache is ordinarily from 70 to 100 gallons, and the boilers between the clarifiers and teache diminiſh in ſize from the firſt to the laſt. Where the clarifiers are in the middle, there is uſually a ſet of three boilers of each ſide, which conſtitute in effect a double boiling-houſe. On very large eſtates this arrangement is found uſeful and neceſſary. The objection to ſo great a number is the expence of fuel; to obviate which, in ſome degree, the three boilers on each ſide of the clarifiers are commonly hung to one fire.

25
The clarifier,

The juice runs from the receiver along a wooden gutter lined with lead into the boiling-houſe, where it is received into one of the clarifiers. When the clarifier is filled, a fire is lighted, and a quantity of Briſtol quicklime in powder, which is called *temper*, is poured into the veſſel. The uſe of the lime is to unite with the ſuperabundant acid, which, for the ſucceſs of the proceſs, it is neceſſary to get rid of. The quantity ſufficient to ſeparate the acid muſt vary according to the ſtrength of the quicklime and the quality of the liquor. Some planters allow a pint of lime to every 100 gallons of liquor; but Mr Edwards thinks that little more than half the quantity is a better medium proportion, and even then, that it ought to be diſſolved in boiling water, that as little of it as poſſible may be precipitated. The heat is ſuffered gradually to increaſe till it approaches within a few degrees of the heat of boiling water, that the impurities

(D) The account given in the text concerning the time when the ſugar-canes are collected, we have taken from the Abbé Raynal's Hiſtory of the Trade and Settlements of the Eaſt and Weſt Indies; but Mr Cazaud obſerves, that in February, March, and April, all the canes, whatever be their age, are as ripe as the nature of the ſoil ever allows them to be. He ſays farther, that the dryneſs of the weather, and not the age of the canes, which increaſes from January to April, is the cauſe that in January 400 gallons of juice commonly yield 48 gallons of ſugar and molaſſes, one with another; in February from 56 to 64; in March from 64 to 72; in April ſometimes 80; after which period the ſugar ferments, and even burns, when the refiner is not very expert at his buſineſs.

Philoſoph. Tranſact. vol. lxix.

Sugar.

purities may be thoroughly feparated. But if the liquor were fuffered to boil with violence, the impurities would again incorporate with it. It is known to be fufficiently heated when the fcum begins to rife in blifters, which break into white froth, and appear generally in about 40 minutes. The fire is then fuddenly extinguifhed by means of a damper, which excludes the external air, and the liquor is allowed to remain about an hour undifturbed, during which period the impurities are collected in fcum on the furface. The juice is then drained off either by a fyphon or a cock; the fcum being of a tenacious gummy nature, does not flow out with the liquor, but remains behind in the clarifier. The liquid juice is conveyed from the clarifier by a gutter into the evaporating boiler, commonly termed the *grand copper;* and if it has been obtained from good canes it generally appears tranfparent.

26
and four coppers.

In the evaporating boiler, which fhould be large enough to receive the contents of the clarifier, the liquor is allowed to boil; and as the fcum rifes it is taken off. The fcumming and evaporation are continued till the liquor becomes finer and thicker, and fo far diminifhed in bulk that it may be eafily contained in the fecond copper. When put into the fecond copper, it is nearly of the colour of Madeira wine; the boiling and fcumming are continued, and if the impurities be confiderable, a quantity of lime-water is added. This procefs is carried on till the liquor be fufficiently diminifhed in quantity to be contained in the third copper. After being purified a third time, it is put into the fourth copper, which is called the *teache*, where it is boiled and evaporated till it is judged fufficiently pure to be removed from the fire. In judging of the purity of the liquor, many of the negroes (fays Mr Edwards) guefs folely by the eye (which by long habit they do with great accuracy), judging by the appearance of the grain on the back of the ladle: but the practice moft in ufe is to judge by what is called the *touch;* i. e. taking up with the thumb a fmall portion of the hot liquor from the ladle; and, as the heat diminifhes, drawing with the fore-finger the liquid into a thread. This thread will fuddenly break, and fhrink from the thumb to the fufpended finger, in different lengths, according as the liquor is more or lefs boiled. The proper boiling height for ftrong mufcovado fugar is generally determined by a thread of a quarter of an inch long. It is evident, that certainty in this experiment can be attained only by long habit, and that no verbal precepts will furnifh any degree of fkill in a matter depending wholly on conftant practice.

27
After being clarified it is cooled, granu'ated, and freed from its melaffes.

The juice being thus purified by paffing through the clarifier and four coppers, it is poured into coolers, which are ufually fix in number. The removal from the teache to the cooler is called *ftriking*. The cooler is a fhallow wooden veffel feven feet long, from five to fix wide, about 11 inches deep, and capable of containing a hogfhead of fugar. As the liquor cools, the fugar grains, that is, collects into an irregular mafs of imperfect cryftals, feparating itfelf from the melaffes. It is then removed from the cooler, and conveyed to the curing-houfe, where the melaffes drain from it. For receiving them there is a large ciftern, the floping fides of which are lined with boards. Directly above the ciftern a frame of joift-work without boarding is placed, on which empty hogfheads without heads are ranged. The bottoms of thefe hogfheads are pierced with 8 or 10 holes, in each of which the ftalk of a plantain leaf is fixed fo as to project fix or eight inches below the joints, and rife a little above the top of the hogfhead. The hogfheads being filled with the contents of the cooler, confifting of fugar and melaffes, the melaffes being liquid, drain through the fpungy ftalk, and drop into the ciftern. After the melaffes are drained off, the fugar becomes pretty dry and fair, and is then called *mufcovado* or *raw fugar*.

We have defcribed the procefs for extracting fugar, which is generally adopted in the Britifh Weft India iflands, according to the lateft improvements; and have been anxious to prefent it to our readers in the fimpleft and moft perfpicuous form, that it might be intelligible to every perfon; and have therefore avoided to mention the obfervations and propofed amendments of thofe who have written on this fubject. Had we done fo, we fhould have fwelled the prefent article to too great a fize, without accomplifhing the purpofe which we hav in view; for our intention is not to inftruct the planters, but to give a diftinct account of the moft approved methods which the planters have generally adopted. But though we judge it ufelefs to trouble our readers with all the little varieties in the procefs which different perfons employ, we flatter ourfelves it will not be difagreeable to learn by what methods the French make their fugar purer and whiter than ours. A quantity of fugar from the cooler is put into conical pans or earthen pots, called by the French *formes*, having a fmall perforation at the apex, which is kept clofed. Each cone, reverfed on its apex, is fupported in another earthen veffel. The fyrup is ftirred together, and then left to cryftallize. At the end of 15 or 16 hours, the hole in the point of each cone is opened, that the impure fyrup may run out. The bafe of thefe fugar loaves is then taken out, and white pulverized fugar fubftituted in its ftead; which being well preffed down, the whole is covered with clay moiftened with water. This water filters through the mafs, carrying the fyrup with it which was mixed with the fugar, but which by this management flows into a pot fubftituted in the place of the firft. This fecond fluid is called *fine fyrup*. Care is taken to moiften and keep the clay to a proper degree of foftnefs as it becomes dry. The fugar loaves are afterwards taken out, and dried in a ftove for eight or ten days; after which they are pulverized, packed, and exported to Europe, where they are ftill farther purified. The reafon affigned why this procefs is not univerfally adopted in the Britifh fugar iflands is this, that the water which dilutes and carries away the melaffes diffolves and carries with it fo much of the fugar, that the difference in quality does not pay for the difference in quantity. The French planters probably think otherwife, upwards of 400 of the plantations of St Domingo having the neceffary apparatus for claying and actually carrying on the fyftem.

28
Method of purifying ufed by the French.

Chaptal's Chemiftry, vol. iii.

29
The art of refining fugar introduced by a Venetian.

The art of refining fugar was firft made known to the Europeans by a Venetian, who is faid to have received 100,000 crowns for the invention. This difcovery was made before the new world was explored; but whether it was an invention of the perfon who firft communicated it, or whether it was conveyed from China, where it had been known for a confiderable time before, cannot now perhaps be accurately afcertained. We find no

Anderfon's Origin of Commerce.

mention made of the refining of fugar in Britain till the year 1659, though it probably was practifed feveral years before. For in the Portuguefe ifland of St Thomas in 1624 there were 74 fugar ingenios, each having upwards of 200 flaves. The quantity of raw fugar imported into England in 1778 amounted to 1,403,995 cwts.; the quantity imported into Scotland in the fame year was 117,285 cwts.; the whole quantity imported into Great Britain in 1787 was 1,926,741 cwts.

30 In refining it is mixed with lime water and bullock's blood, and expofed to heat.

The fugar which undergoes the operation of refining in Europe is either raw fugar, fometimes called *mufcovado* or *caffonado*, which is raw fugar in a purer ftate. The raw fugar generally contains a certain quantity of melaffes as well as earthy and feculent fubftances. The caffonado, by the operation of earthing, is freed from its melaffes. As the intention of refining thefe fugars is to give them a higher degree of whitenefs and folidity, it is neceffary for them to undergo other proceffes. The firft of thefe is called *clarification*. It confifts in diffolving the fugar in a certain proportion of lime-water, adding a proper quantity of bullock's blood, and expofing it to heat in order to remove the impurities which ftill remain. The heat is increafed very gradually till it approach that of boiling water. By the affiftance of the heat, the animal matter which was thrown in coagulates, at the fame time that it attracts all the folid feculent and earthy matter, and raifes it to the furface in the appearance of a thick foam of a brownifh colour. As the feculencies are never entirely removed by a firft procefs, a fecond is neceffary. The folution is therefore cooled to a certain degree by adding fome water; then a frefh quantity of blood, but lefs confiderable than at firft, is poured in. The fire is renewed, and care is taken to increafe the heat gently as before. The animal fubftance feizes on the impurities which remain, collects them on the furface, and they are then fkimmed off. The fame operation is repeated a third and even a fourth time, but no addition is made to the liquor except water. If the different proceffes have been properly conducted, the folution will be freed from every impurity, and appear tranfparent. It is then conveyed by a gutter into an oblong bafket about 16 inches deep, lined with a woollen cloth; and after filtering through this cloth, it is received in a ciftern or copper which is placed below.

31 Then freed from its remaining impurities by evaporation.

The folution being thus clarified, it undergoes a fecond general operation called *evaporation*. Fire is applied to the copper into which the folution was received, and the liquid is boiled till it has acquired the proper degree of confiftency. A judgement is formed of this by taking up a fmall portion of the liquid and drawing it into a thread. When, after this trial, it is found fufficiently vifcous, the fire is extinguifhed, and the liquid is poured into coolers. It is then ftirred violently by an inftrument called an *oar*, from the refemblance it bears to the oar of a boat. This is done in order to diminifh the vifcofity, and promote what is called the *granulation*, that is, the forming of it into grains or imperfect cryftals. When the liquid is properly mixed and cooled, it is then poured into moulds of the form of a fugar loaf. Thefe moulds are ranged in rows. The fmall ends, which are loweft, are placed in pots; and they have each of them apertures ftopped up with linen for filtering the fyrup, which runs from the moulds into the pots. The liquor is then taken out flowly in ladlefuls from the coolers, and poured into the moulds. When the moulds are filled, and the contents ftill in a fluid ftate, it is neceffary to ftir them, that no part may adhere to the moulds, and that the fmall cryftals which are juft formed may be equally diffufed through the whole mafs. When the fugar is completely cryftallized, the linen is taken away from the apertures in the moulds, and the fyrup, or that part which did not cryftallize, defcends into the pots in which the moulds are placed. After this purgation the moulds are removed and fixed in other pots, and a ftratum of fine white clay diluted with water is laid on the upper part of the loaf. The water defcending through the fugar by its own weight, mixes with the fyrup which ftill remains in the body of the loaf, and wafhes it away. When the clay dries, it is taken off, and another covering of moift clay put in its place; and if it be not then fufficiently wafhed, a third covering of clay is applied. After the loaves have ftood fome days in the moulds, and have acquired a confiderable degree of firmnefs and folidity, they are taken out, and carried to a ftove, where they are gradually heated to the 50° of Reaumur (64° of Fahrenheit), in order to diffipate any moifture which may be ftill confined in them. After remaining in the ftove eight days, they are taken out; and after cutting off all difcolouring fpecks, and the head if ftill wet, they are wrapped in blue paper, and are ready for fale. The feveral fyrups collected during the different parts of the procefs, treated in the fame manner which we have juft defcribed, afford fugars of inferior quality; and the laft portion, which no longer affords any fugar, is fold by the name of *melaffes*.

32 Afterwards poured into moulds, where the fyrup is drained from it.

33 Laftly expofed to a certain degree of heat.

34 In what the beauty of fugar confifts; how farther refined.

The beauty of refined fugar, when formed into loaves, confifts in whitenefs, joined to a fmallnefs of grain; in being dry, hard, and fomewhat tranfparent. The procefs which we have defcribed above refers to fugar once refined; but fome more labour is neceffary to produce double refined fugar. The principal difference in the operation is this, the latter is clarified by white of eggs inftead of blood, and frefh water in place of lime-water.

35 How fugar-candy is made.

Sugar-candy is the true effence of the cane formed into large cryftals by a flow procefs. When the fyrup is well clarified, it is boiled a little, but not fo much as is done for the proof mentioned in the procefs for making common fugar. It is then placed in old moulds, having their lower ends ftopped with linen, and croffed at little diftances with fmall twigs to retain the fugar as it cryftallizes. The moulds are then laid in a cool place. In proportion as the fyrup cools cryftals are formed. In about nine or ten days the moulds are carried to the ftove, and placed in a pot; but the linen is not removed entirely, fo that the fyrup falls down flowly in drops. When the fyrup has dropped away, and the cryftals of the fugar-candy are become dry, the moulds are taken from the ftove and broken in pieces, to difengage the fugar, which adheres ftrongly to the fides of the moulds. If the fyrup has been coloured with cochineal, the cryftals take a flight taint of red; if indigo has been mixed, they affume a bluifh colour. If it be defired to have the candy perfumed, the effence of flowers or amber may be dropped into the moulds along with the fyrup.

Having now given fome account of the method ufually employed for refining fugar, it will not be improper

Sugar. proper to ſay a few things concerning its nature and its uſes.

36 Chemical qualities of ſugar.

Sugar is ſoluble in water, and in a ſmall degree in alcohol. When united with a ſmall portion of water, it becomes fuſible; from which quality the art of preſerving is indebted for many of its preparations. It is phoſphoric and combuſtible; when expoſed to fire emitting a blue flame if the combuſtion be ſlow, and a white flame if the combuſtion be rapid. By diſtillation it produces a quantity of phlegm, acid, oil, gas, and charcoal. Bergman, in treating ſugar with the nitrous acid, obtained a new acid now known by the name of the *oxalic acid:* but he has omitted to mention the principles of which ſugar is compoſed. Lavoiſier, however, has ſupplied this omiſſion; and after many experiments has aſſigned three principles in ſugar, hydrogen, oxygen, and carbone. If the juice expreſſed from the ſugar-cane be left to itſelf, it paſſes into the acetous fermentation; and during the decompoſition of the ſugar, which is continued for three or four months, a great quantity of glutinous matter is ſeparated. This matter when diſtilled gives a portion of ammoniac. If the juice be expoſed to the ſpirituous fermentation, a wine is obtained analogous to cyder. If this wine, after being kept in bottles a-year, be diſtilled, we obtain a portion of *eau de vie.*

37 Its uſes in medicine, &c.

The uſes to which ſugar are applied are indeed numerous and important: It can be made ſo ſolid as in the art of preſerving to receive the moſt agreeable colours and the greateſt variety of forms. It can be made ſo fluid as to mix with any ſoluble ſubſtance.—It preſerves the juice and ſubſtance of fruits in all countries and in all ſeaſons. It affords a delicious ſeaſoning to many kinds of food. It is uſeful in pharmacy, for it unites with medicines, and removes their diſagreeable flavour: it is the baſis of all ſyrups. M. Macquer has ſhown in a very ſatisfactory manner how uſeful ſugar would be if employed in fermenting wines. Sugar has alſo been found a remedy for the ſcurvy, and a valuable article of food in caſes of neceſſity. M. Imbert de Lennes, firſt ſurgeon to the late duke of Orleans, publiſhed the following ſtory in the *Gazette de Santé*, which confirms this aſſertion. A veſſel laden with ſugar bound from the Weſt Indies was becalmed in its paſſage for ſeveral days, during which the ſtock of proviſions was exhauſted. Some of the crew were dying of the ſcurvy, and the reſt were threatened with a ſtill more terrible death. In this emergency recourſe was had to the ſugar. The conſequence was, the ſymptoms of the ſcurvy went off, the crew found it a wholeſome and ſubſtantial aliment, and returned in good health to France.

38 Affords the greateſt quantity of nouriſhment of any kind of food.

"Sugar (ſays Dr Ruſh) affords the greateſt quantity of nouriſhment in a given quantity of matter of any ſubſtance in nature; of courſe it may be preſerved in leſs room in our houſes, and may be conſumed in leſs time, than more bulky and leſs nouriſhing aliment. It has this peculiar advantage over moſt kinds of aliment, that it is not liable to have its nutritious qualities affected by time or the weather; hence it is preferred by the Indians in their excurſions from home. They mix a certain quantity of maple ſugar, with an equal quantity of Indian corn, dried and powdered, in its milky ſtate. This mixture is packed in little baſkets, which are frequently wetted in travelling, without injuring the ſugar. A few ſpoonfuls of it mixed with half a pint of ſpring water afford them a pleaſant and ſtrengthening meal. From the degrees of ſtrength and nouriſhment which are conveyed into animal bodies by a ſmall bulk of ſugar, it might probably be given to horſes with great advantage, when they are uſed in places or under circumſtances which make it difficult or expenſive to ſupport them with more bulky or weighty aliment. A pound of ſugar with graſs or hay has ſupported the ſtrength and ſpirits of a horſe during a whole day's labour in one of the Weſt-India iſlands. A larger quantity given alone has fattened horſes and cattle, during the war before laſt in Hiſpaniola, for a period of ſeveral months, in which the exportation of ſugar, and the importation of grain, were prevented by the want of ſhips.

Tranſactions of the American Philoſophical Society, vol. iii.

39 An excellent antidote againſt worms.

"The plentiful uſe of ſugar in diet is one of the beſt preventives that has ever been diſcovered of the diſeaſes which are produced by worms. Nature ſeems to have implanted a love for this aliment in all children, as if it were on purpoſe to defend them from thoſe diſeaſes. Dr Ruſh knew a gentleman in Philadelphia, who early adopted this opinion, and who, by indulging a large family of children in the uſe of ſugar, has preſerved them all from the diſeaſes uſually occaſioned by worms.

40 and probably againſt the plague and other malignant fevers.

"Sir John Pringle has remarked, that the plague has never been known in any country where ſugar compoſes a material part of the diet of the inhabitants. Dr Ruſh thinks it probable that the frequency of malignant fevers of all kinds has been leſſened by this diet, and that its more general uſe would defend that claſs of people who are moſt ſubject to malignant fevers from being ſo often affected by them.

"In the numerous and frequent diſorders of the breaſt, which occur in all countries where the body is expoſed to a variable temperature of weather, ſugar affords the baſis of many agreeable remedies. It is uſeful in weakneſſes, and acrid defluxions upon other parts of the body. Many facts may be adduced in favour of this aſſertion. Dr Ruſh mentions only one, which, from the venerable name of the perſon whoſe caſe furniſhed it, cannot fail of commanding attention and credit. Upon my inquiring of Dr Franklin, at the requeſt of a friend (ſays our reſpectable author), about a year before he died, whether he had found any relief from the pain of the ſtone from the blackberry jam, of which he took large quantities, he told me that he had, but that he believed the medicinal part of the jam reſided wholly in the ſugar; and as a reaſon for thinking ſo, he added, that he often found the ſame relief by taking about half a pint of a ſyrup, prepared by boiling a little brown ſugar in water, juſt before he went to bed, that he did from a doſe of opium. It has been ſuppoſed by ſome of the early phyſicians of our country, that the ſugar obtained from the maple-tree is more medicinal than that obtained from the Weſt India ſugar-cane; but this opinion I believe is without foundation. It is preferable in its qualities to the Weſt India ſugar only from its ſuperior cleanlineſs.

41 Has given relief from the pain of the ſtone.

"Caſes may occur in which ſugar may be required in medicine, or in diet, by perſons who refuſe to be benefited, even indirectly by the labour of ſlaves. In ſuch caſes the innocent maple ſugar will always be preferred. It has been ſaid, that ſugar injures the teeth; but this opinion now has ſo few advocates, that it does not deſerve a ſerious refutation."

42 Not hurtful to the teeth.

In

In the account which we have given above of the method of cultivating and manufacturing ſugar, we have had in our eye the plantations in the Weſt Indies, where ſlaves alone are employed; but we feel a peculiar pleaſure in having it in our power to add a ſhort deſcription of the method uſed in the Eaſt Indies, becauſe there ſugar is manufactured by free men, on a plan which is much more economical than what is followed in the Weſt Indies. The account which we mean to give is an extract from the report of the committee of Privy-council for trade on the ſubject of the African ſlave-trade, drawn up by Mr Botham. We ſhall give it in the author's own words.

43
Sugar manufactured in the Eaſt Indies by free men,

"Having been for two years in the Engliſh and French Weſt India iſlands, and ſince conducted ſugar eſtates in the Eaſt Indies; before the abolition of the ſlave-trade was agitated in parliament, it may be deſirable to know that ſugar of a ſuperior quality and inferior price to that in our iſlands is produced in the Eaſt Indies; that the culture of the cane, the manufacture of the ſugar and arrack, is, with theſe material advantages, carried on by free people. China, Bengal, the coaſt of Malabar, all produce quantities of ſugar and ſpirits; but as the moſt conſiderable growth of the cane is carried on near Batavia, I ſhall explain the improved manner in which ſugar eſtates are there conducted. The proprietor of the eſtate is generally a wealthy Dutchman, who has erected on it ſubſtantial mills, boiling and curing houſes. He rents this eſtate to a Chineſe, who reſides on it as a ſuperintendant; and this renter (ſuppoſing the eſtate to conſiſt of 300 or more acres) relets it to free men in parcels of 50 or 60 on theſe conditions: "That they ſhall plant it in canes, and receive ſo much per pecul of $133\frac{1}{3}$ pounds for every pecul of ſugar that the canes ſhall produce."

44
of a ſuperior quality and at a lower price.

45
How ſugar eſtates are managed at Batavia.

When crop time comes on, the ſuperintendant collects a ſufficient number of perſons from the adjacent towns or villages, and takes off his crop as follows. To any ſet of tradeſmen who bring their carts and buffaloes he agrees to give ſuch a price per pecul to cut all his crop of canes, carry them to the mill and grind them. A ſecond to boil them per pecul. A third to clay them and baſket them for market per pecul. So that by this method of conducting a ſugar eſtate the renter knows to a certainty what the produce of it will coſt him per pecul. He has not any permanent or unneceſſary expence; for when the crop is taken off, the taſkmen return to their ſeveral purſuits in the towns and villages they came from; and there only remain the cane planters who are preparing the next year's crop. This like all other complex arts, by being divided into ſeveral branches, renders the labour cheaper and the work more perfectly done.

Only clayed ſugars are made at Batavia; theſe are in quality equal to the beſt ſort from the Weſt Indies, and are ſold ſo low from the ſugar eſtates as eighteen ſhillings ſterling per pecul of $133\frac{1}{3}$libs. This is not the ſelling price to the trader at Batavia, as the government there is arbitrary, and ſugar ſubject to duties impoſed at will. The Shabander exacts a dollar per pecul on all ſugar exported. The price of common labour is from 9d. to 10d. per day. By the method of carrying on the ſugar eſtates, the taſkmen gain conſiderably more than this not only from working extraordinary hours, but from being conſidered artiſts in their ſeveral branches. They do not make ſpirits on the ſugar eſtates. The melaſſes is ſent for ſale to Batavia, where one diſtillery may purchaſe the produce of an hundred eſtates. Here is a vaſt ſaving and reduction of the price of ſpirits; not as in the Weſt Indies, a diſtillery, for each eſtate; many centre in one, and arrack is ſold at Batavia from 21 to 25 rixdollars per leaguer of 160 gallons; ſay 8d. per gallon."

46
Deſcription of the ſugar maple.

The SUGAR MAPLE, (the *acer ſaccharinum* of Linnæus), as well as the ſugar-cane, produces a great quantity of ſugar. This tree grows in great numbers in the weſtern counties of all the middle ſtates of the American union. Thoſe which grow in New York and Pennſylvania yield the ſugar in a greater quantity than thoſe which grow on the waters of the Ohio.—Theſe trees are generally found mixed with the beech, hemlock, white and water aſh, the cucumber tree, linden, aſpen, butter nut, and wild cherry trees. They ſometimes appear in groves covering five or ſix acres in a body, but they are more commonly interſperſed with ſome or all of the foreſt trees which have been mentioned. From 30 to 50 trees are generally found upon an acre of ground. They grow only in the richeſt ſoils, and frequently in ſtony ground. Springs of the pureſt water abound in their neighbourhood. They are, when fully grown, as tall as the white and black oaks, and from two to three feet in diameter. They put forth a beautiful white bloſſom in the ſpring before they ſhow a ſingle leaf. The colour of the bloſſom diſtinguiſhes them from the acer rubrum, or the common maple, which affords a bloſſom of a red colour. The wood of the ſugar maple-tree is extremely inflammable, and is preferred upon that account by hunters and ſurveyors for fire-wood. Its ſmall branches are ſo much impregnated with ſugar as to afford ſupport to the cattle, horſes, and ſheep of the firſt ſettlers, during the winter, before they are able to cultivate forage for that purpoſe. Its aſhes afford a great quantity of potaſh, exceeded by few, or perhaps by none, of the trees that grow in the woods of the United States. The tree is ſuppoſed to arrive at its full growth in the woods in twenty years.

Tranſactions of the American Philoſophical Society, vol. iii.

47
The oftener this tree is tapped the more ſyrup is obtained from it.

It is not injured by tapping; on the contrary, the oftener it is tapped, the more ſyrup is obtained from it. In this reſpect it follows a law of animal ſecretion. A ſingle tree had not only ſurvived, but flouriſhed after forty-two tappings in the ſame number of years. The effects of a yearly diſcharge of ſap from the tree, in improving and increaſing the ſap, are demonſtrated from the ſuperior excellence of thoſe trees which have been perforated in an hundred places, by a ſmall wood-pecker which feeds upon the ſap. The trees, after having been wounded in this way, diſtil the remains of their juice on the ground, and afterwards acquire a black colour. The ſap of theſe trees is much ſweeter to the taſte than that which is obtained from trees which have not been previouſly wounded, and it affords more ſugar.

48
What quantity of ſap will produce a certain quantity of ſugar.

From twenty-three gallons and one quart of ſap, procured in twenty-four hours from only two of theſe dark coloured trees, Arthur Noble, Eſq. of the ſtate of New York, obtained four pounds and thirteen ounces of good grained ſugar.

A tree of an ordinary ſize yields in a good ſeaſon from twenty to thirty gallons of ſap, from which are made from five to ſix pounds of ſugar. To this there are ſometimes

Sugar. times remarkable exceptions. Samuel Lowe, Esq. a justice of peace in Montgomery county, in the state of New York, informed Arthur Noble, Esq. that he had made twenty pounds and one ounce of sugar between the 14th and 23d of April, in the year 1789, from a single tree that had been tapped for several successive years before.

49 This quantity might be increased by culture. From the influence which culture has upon forest and other trees, it has been supposed, that by transplanting the sugar maple-tree into a garden, or by destroying such other trees as shelter it from the rays of the sun, the quantity of the sap might be increased, and its quality much improved. A farmer in Northampton county, in the state of Pennsylvania, planted a number of these trees above twenty years ago in his meadow, from three gallons of the sap of which he obtains every year a pound of sugar. It was observed formerly, that it required five or six gallons of the sap of the trees which grow in the woods to produce the same quantity of sugar.

50 The sap distils from the wood in the spring months. The sap distils from the wood of the tree. Trees which have been cut down in the winter for the support of the domestic animals of the new settlers, yield a considerable quantity of sap as soon as their trunks and limbs feel the rays of the sun in the spring of the year. It is in consequence of the sap of these trees being equally diffused through every part of them, that they live three years after they are girdled, that is, after a circular incision is made through the bark into the substance of the tree for the purpose of destroying it. It is remarkable that grass thrives better under this tree in a meadow, than in situations exposed to the constant action of the sun. The season for tapping the trees is in February, March, and April, according to the weather which occurs in these months.

51 Is increased by warm days and frosty nights. Warm days and frosty nights are most favourable to a plentiful discharge of sap. The quantity obtained in a day from a tree is from five gallons to a pint, according to the greater or less heat of the air. Mr Lowe informed Arthur Noble, Esq. that he obtained near three and twenty gallons of sap in one day (April 14. 1789.) from the single tree which was before mentioned. Such instances of a profusion of sap in single trees are however not very common.

52 How the sap is drained from the tree. There is always a suspension of the discharge of sap in the night if a frost succeed a warm day. The perforation in the tree is made with an axe or an auger. The latter is preferred from experience of its advantages. The auger is introduced about three quarters of an inch, and in an ascending direction (that the sap may not be frozen in a slow current in the mornings or evenings), and is afterwards deepened gradually to the extent of two inches. A spout is introduced about half an inch into the hole made by this auger, and projects from three to twelve inches from the tree. The spout is generally made of the sumach or elder, which usually grows in the neighbourhood of the sugar trees. The tree is first tapped on the south side; when the discharge of its sap begins to lessen, an opening is made on the north side, from which an increased discharge takes place. The sap flows from four to six weeks, according to the temperature of the weather. Troughs large enough to contain three or four gallons made of white pine, or white ash, or of dried water ash, aspen, linden, poplar, or common maple, are placed under the spout to receive the sap, which is carried every day to a large receiver, made of either of the trees before mentioned. From this receiver it is conveyed, after being strained, to the boiler.

Sugar || Sugillation.

53 Is reduced to sugar by three modes. We understand that there are three modes of reducing the sap to sugar; by evaporation, by freezing, and by boiling; of which the latter is most general, as being the most expeditious. We are farther assured, that the profit of the maple tree is not confined to its sugar. It affords most agreeable melasses, and an excellent vinegar. The sap which is suitable for these purposes is obtained after the sap which affords the sugar has ceased to flow, so that the manufactories of these different products of the maple tree, by succeeding, do not interfere with each other. The melasses may be made to compose the basis of a pleasant summer beer. The sap of the maple is moreover capable of affording a spirit; but we hope this precious juice will never be prostituted to this ignoble purpose. Should the use of sugar in diet become more general in this country (says Dr Rush) it may tend to lessen the inclination or supposed necessity for spirits, for I have observed a relish for sugar in diet to be seldom accompanied by a love for strong drink.

54 Sugar procured from many other vegetables. There are several other vegetables raised in our own country which afford sugar; as beet-roots, skirrets, parsneps, potatoes, celeri, red cabbage stalks, the young shoots of Indian wheat. The sugar is most readily obtained from these, by making a tincture of the subject in rectified spirit of wine; which, when saturated by heat, will deposit the sugar upon standing in the cold.

Sugar of Milk. See Milk, Chemistry *Index*.

Acid of Sugar. See Chemistry *Index*.

SUGILLATION, in *Medicine*, an extravasation of blood in the coats of the eye, which at first appears of a reddish colour, and afterwards livid or black. If the disorder is great, bleeding and purging are proper, as are also discutients.
